January 2, 2026

Abstract

Theorem. The type system (B, S) (Bases and Namespace) is the unique minimal complete representation of class-based object semantics.

Proof structure:

1. *Completeness:* (B, S) answers all typing queries. Type names add no information; they are computable from (B, S) .
2. *Minimality:* Neither B nor S alone suffices. Provenance requires B . Membership requires S . Removing either axis makes some query unanswerable.
3. *Uniqueness:* Any complete system contains (B, S) or is isomorphic to it. There is no alternative.

Principal results (machine-checked, 0 sorries):

- **Theorem 3.13 (Provenance Impossibility):** No system without B can compute provenance. This is information-theoretic: the input lacks the data.
- **Theorem 3.19 (Capability Partition):** The set of queries partitions exactly into S -sufficient and B -required. Tertium non datur.
- **Theorem 3.24 (Error Localization Lower Bound):** Duck typing requires $\Omega(n)$ inspections to localize errors. Nominal typing achieves $O(1)$. The gap is unbounded.
- **Theorem (Minimality \Rightarrow Orthogonality):** Every minimal complete axis set is orthogonal. Non-orthogonal systems contain redundancy and are therefore not minimal.

Novel Axis H (Hierarchy):

 For systems with containment trees, we prove:

- **Theorem 3.61 (H Necessity):** There exist queries answerable with H that are impossible without H . This is information-theoretic: (B, S) lacks the data.
- **Theorem 3.62 (H Orthogonality):** H is not derivable from B or S . No lattice homomorphism exists. H is a genuinely new axis.
- **Theorem 3.63 (Uniqueness):** (B, S, H) is the unique minimal complete system for hierarchical configuration. There is no alternative.

Central Result (Axis Derivation): Axes are not designed. They are *derived* from domain requirements. B emerges when the domain requires provenance. S emerges when the domain requires membership. H emerges when the domain requires hierarchical visibility. The framework computes the minimal complete axis set for any domain.

Implications:

1. **Strict dominance.** Unused axes have zero cost. Nominal typing includes B . If provenance is needed, B is required. If not needed, B costs nothing. Nominal strictly dominates structural unconditionally.
2. **Duck typing.** Duck typing is the empty axis set $A = \emptyset$. It answers zero typing queries. Error localization is $\Omega(n)$; nominal achieves $O(1)$. The gap is unbounded.
3. **Uniqueness.** For any domain D , the minimal complete axis set A_D is unique and computable from D .
4. **Fixed axis sets.** A type system with fixed axis set A is incomplete for domains requiring axes outside A . Incompleteness is certain for some domain.
5. **Parametric completeness.** A type system is complete for all domains iff parameterized: $\forall A. \text{TypeSystem}(A)$. The API is uniform across axis sets. Query answering is $O(k)$ for k axes. Orthogonality guarantees no axis interaction in query evaluation.
6. **Axis derivation.** $D \mapsto A_D$ is deterministic. Axes are computed, not chosen.

Corollary (Forced Solution): For any domain D , Theorem 3.63 establishes existential uniqueness: $\exists! A$ such that $\text{minimal}(A, D)$. This makes the typing discipline mathematically determined, not designed. Given completeness and minimality as requirements, the solution is forced by the domain structure. Claiming “typing discipline is a matter of preference” while accepting the uniqueness theorem instantiates $P \wedge \neg P$: uniqueness entails $\neg \exists$ alternatives; preference presupposes \exists alternatives. The mathematics admits no choice.

All proofs in Lean 4 (2700+ lines, 142+ theorems, 0 **sorry**).

Keywords: type systems, nominal typing, structural typing, matroid theory, impossibility theorems, formal verification

1 Introduction

1.1 Metatheoretic Foundations

This work follows the tradition of Liskov & Wing [18], who formalized correctness criteria for subtyping in their foundational TOPLAS paper. Where Liskov & Wing asked “what makes subtyping *correct*?”, we ask “what makes typing discipline selection *correct*?”

Our contribution is not recommending specific typing disciplines, but deriving what constitutes a correct choice from formal requirements. We prove the (B, S) model (Bases and Namespace) **completes** the semantic structure of class-based object-oriented systems, enabling derivation rather than preference-based selection.

1.2 Overview

This paper proves that for object-oriented systems with inheritance hierarchies, typing discipline selection is **derivable** from requirements rather than a matter of preference. All results are machine-checked in Lean 4 (2600+ lines, 127 theorems, 0 **sorry** placeholders).

We develop a metatheory of class system design applicable to any language with explicit inheritance. The core insight: every class system is characterized by which axes of the (B, S) model it employs; names are syntactic sugar and contribute no observables. These axes form a recursive lattice: $\emptyset < S < (B, S)$, where each increment strictly dominates the previous. For runtime context systems, the model extends to (B, S, Scope) , a third orthogonal axis capturing hierarchical containment (e.g., global \rightarrow module \rightarrow function).

The pay-as-you-go principle: Each axis increment adds capabilities without cognitive load increase until those capabilities are invoked. Duck typing uses S ; nominal uses (B, S) with the same `isinstance()` API; scoped resolution uses (B, S, Scope) with one optional parameter.

The model formalizes what programmers intuitively understand but rarely make explicit:

1. **Universal dominance** (Theorem 3.4): For languages with explicit inheritance (**bases** axis), nominal typing Pareto-dominates structural typing in greenfield development (provides strictly more capabilities with zero tradeoffs). Structural typing is appropriate only when **bases** = [] universally (e.g., Go) or in retrofit/interop scenarios. The decision is **derived** from capability analysis, not preference.
2. **Complexity separation** (Theorem 4.3): Nominal typing achieves $O(1)$ error localization; duck typing requires $\Omega(n)$ call-site inspection.
3. **Provenance impossibility** (Corollary 6.3): Duck typing cannot answer “which type provided this value?” because structurally equivalent objects are indistinguishable by definition. Machine-checked in Lean 4.

These theorems yield four measurable code quality metrics:

Metric	What it measures	Indicates
Duck typing density	<code>hasattr()</code> per KLOC	Discipline violations (duck typing is incoherent per Theorem 2.10d; other <code>getattr()</code> / <code>AttributeError</code> patterns may be valid metaprogramming)
Nominal typing ratio	<code>isinstance()</code> + ABC registrations per KLOC	Explicit type contracts
Provenance capability	Presence of “which type provided this” queries	System requires nominal typing
Resolution determinism	MRO-based dispatch vs runtime probing	$O(1)$ vs $\Omega(n)$ error localization

The methodology is validated through case studies from OpenHCS [31], a production bioimage analysis platform. The system’s architecture exposed the formal necessity of nominal typing through patterns ranging from metaclass auto-registration to bidirectional type registries. A migration from duck typing to nominal contracts (PR #44 [32]) eliminated 47 scattered `hasattr()` checks and consolidated dispatch logic into explicit ABC contracts.

1.3 Contributions

This paper makes five contributions:

1. **Universal Theorems (Section 3.8):** - **Theorem 3.13 (Provenance Impossibility):** No shape discipline can compute provenance (information-theoretically impossible). - **Theorem 3.19 (Derived Characterization):** Capability gap = B-dependent queries (derived from query space partition, not enumerated). - **Theorem 3.24 (Complexity Lower Bound):** Duck typing requires $\Omega(n)$ inspections (proved by adversary argument). - These theorems make claims about the universe of possible systems through information-theoretic analysis, mathematical partition, and adversary arguments.

2. **Completeness and Robustness Theorems (Section 3.11):** - **Theorem 3.32 (Model Completeness):** (B, S) captures all runtime-available type information. - **Theorem 3.34-3.35 (Capability Comparison):** $\mathcal{C}_{\text{duck}} \subsetneq \mathcal{C}_{\text{nom}}$. Nominal provides all duck typing capabilities plus four additional. - **Lemma 3.37 (Axiom Justification):** Shape axiom is definitional, not assumptive. - **Theorem 3.39 (Extension Impossibility):** No computable extension to duck typing recovers provenance. - **Theorems 3.43-3.47 (Generics):** Type parameters refine N , not a fourth axis. All theorems extend to generic types. Erasure is irrelevant (type checking at compile time). - **Non-Claims 3.41-3.42, Claim 3.48 (Scope):** Explicit limits and claims.

3. Metatheoretic foundations (Sections 2-3): - The two-axis model (B, S) as a universal framework for class systems (names are syntactic sugar) - Theorem 2.15 (Axis Lattice Dominance): capability monotonicity under axis subset ordering - Theorem 2.17 (Capability Completeness): the capability set \mathcal{C}_B is exactly four elements (complete) - Theorem 3.5: Nominal typing strictly dominates shape-based typing universally (when $B \neq \emptyset$)

4. Machine-checked verification (Section 6): - 2600+ lines of Lean 4 proofs across five modules - 127 theorems/lemmas covering typing, architecture, information theory, complexity bounds, impossibility, lower bounds, completeness analysis, generics, exotic features, universal scope, discipline vs migration separation, context formalization, capability exhaustiveness, and adapter amortization - Formalized $O(1)$ vs $O(k)$ vs $O(n)$ complexity separation with adversary-based lower bound proof - Universal extension to 8 languages (Java, C#, Rust, TypeScript, Kotlin, Swift, Scala, C++) - Exotic type features covered (intersection, union, row polymorphism, HKT, multiple dispatch) - **Zero sorry placeholders (all 127 theorems/lemmas complete)**

5. Empirical validation (Section 5): - 13 case studies from OpenHCS (45K LoC production Python codebase) - Demonstrates theoretical predictions align with real-world architectural decisions - Four derivable code quality metrics (DTD, NTR, PC, RD)

1.3.1 Empirical Context: OpenHCS

What it does: OpenHCS is a bioimage analysis platform. Pipelines are compiled before execution. Errors surface at definition time, not after processing starts. The GUI and Python code are interconvertible: design in GUI, export to code, edit, re-import. Changes to parent config propagate automatically to all child windows.

Why it matters for this paper: The system requires knowing *which type* provided a value, not just *what* the value is. Dual-axis resolution walks both the context hierarchy (global \rightarrow plate \rightarrow step) and the class hierarchy (MRO) simultaneously. Every resolved value carries provenance: (value, source_scope, source_type). This is only possible with nominal typing. Duck typing cannot answer “which type provided this?”

Key architectural patterns (detailed in Section 5): - `@auto_create_decorator \rightarrow @global_pipeline_configcascade : onedecoratorspawns a5 - stagetypetransformation(CaseStudy7) - Dual - axisresolver : MRO is the priority system. No custom priority function exists(CaseStudy8) - Bidirectional typeregistries : single source of truth with type() identity as key(CaseStudy13)`

1.3.2 Decision Procedure, Not Preference

The contribution of this paper is not the theorems alone, but their consequence: typing discipline selection becomes a decision procedure. Given requirements, the discipline is derived.

Implications:

1. Pedagogy. Architecture courses should not teach “pick the style that feels Pythonic.” They should teach how to derive the correct discipline from requirements. This is engineering, not taste.
2. AI code generation. LLMs can apply the decision procedure. “Given requirements R, apply Algorithm 1, emit code with the derived discipline” is an objective correctness criterion. The model either applies the procedure correctly or it does not.
3. Language design. Future languages could enforce discipline based on declared requirements. A `@requires_provenance` annotation could mandate nominal patterns at compile time.
4. Formal constraints. When requirements include provenance, the mathematics constrains the choice: shape-based typing cannot provide this capability (Theorem 3.13, information-theoretic impossibility). The procedure derives the discipline from requirements.

1.3.3 Scope and Limitations

This paper makes absolute claims. We do not argue nominal typing is “preferred” or “more elegant.” We prove:

1. Shape-based typing cannot provide provenance. Duck typing and structural typing check type *shape*: attributes, method signatures. Provenance requires type *identity*. Shape-based disciplines cannot provide what they do not track.
2. When $B \neq \emptyset$, nominal typing dominates. Nominal typing provides strictly more capabilities. Adapters eliminate the retrofit exception (Theorem 2.10j). When inheritance exists, nominal typing is the capability-maximizing choice.
3. Shape-based typing is a capability sacrifice. Protocol and duck typing discard the Bases axis. This eliminates four capabilities (provenance, identity, enumeration, conflict resolution) without providing any compensating capability (a dominated choice when $B \neq \emptyset$).

Boundary scope (pulled forward for clarity): when $B = \emptyset$ (no user-declared inheritance), e.g., pure JSON/FFI payloads or languages intentionally designed without inheritance. Structural typing is the coherent choice. Our dominance claims apply whenever $B \neq \emptyset$ and inheritance metadata is accessible; FFI or opaque-runtime boundaries that erase B fall outside the claim.

We do not claim all systems require provenance. We prove that systems requiring provenance cannot use shape-based typing. The requirements are the architect’s choice; the discipline, given requirements, is derived.

1.4 Roadmap

Section 2: Metatheoretic foundations -- The two-axis model (B, S) with names as sugar, abstract class system formalization, and the Axis Lattice Metatheorem (Theorem 2.15)

Section 3: Universal dominance -- Strict dominance (Theorem 3.5), information-theoretic completeness (Theorem 3.19), retrofit exception eliminated (Theorem 2.10j)

Section 4: Decision procedure -- Deriving typing discipline from system properties

Section 5: Empirical validation -- 13 OpenHCS case studies validating theoretical predictions

Section 6: Machine-checked proofs -- Lean 4 formalization (2600+ lines)

Section 7: Related work -- Positioning within PL theory literature

Section 8: Extensions -- Mixins vs composition (Theorem 8.1), TypeScript coherence analysis (Theorem 8.7), gradual typing connection, Zen alignment

Section 9: Conclusion -- Implications for PL theory and practice

2 Preliminaries

2.1 Definitions

Definition 2.1 (Class). A class C is a triple (name, bases, namespace) where: - name $\in \text{String}$ -- the identity of the class - bases $\in \text{List}[\text{Class}]$ -- explicit inheritance declarations - namespace $\in \text{Dict}[\text{String}, \text{Any}]$ -- attributes and methods

Definition 2.2 (Typing Discipline). A typing discipline T is a method for determining whether an object x satisfies a type constraint A .

Definition 2.3 (Nominal Typing). x satisfies A iff $A \in \text{MRO}(\text{type}(x))$. The constraint is checked via explicit inheritance.

Definition 2.4 (Structural Typing). x satisfies A iff $\text{namespace}(x) \supseteq \text{signature}(A)$. The constraint is checked via method/attribute matching. In Python, `typing.Protocol` implements structural typing: a class satisfies a Protocol if it has matching method signatures, regardless of inheritance.

Definition 2.5 (Duck Typing). x satisfies A iff `hasattr(x, m)` returns `True` for each m in some implicit set M . The constraint is checked via runtime string-based probing.

Observation 2.1 (Shape-Based Typing). Structural typing and duck typing are both *shape-based*: they check what methods or attributes an object has, not what type it is. Nominal typing is *identity-based*: it checks the inheritance chain. This distinction is fundamental. Python’s Protocol, TypeScript’s interfaces, and Go’s implicit interface satisfaction are all shape-based. ABCs with explicit inheritance are identity-based. The theorems in this paper prove shape-based typing cannot provide provenance--regardless of whether the shape-checking happens at compile time (structural) or runtime (duck).

Complexity distinction: While structural typing and duck typing are both shape-based, they differ critically in *when* the shape-checking occurs:

- Structural typing (Protocol): Shape-checking at *static analysis time* or *type definition time*. Complexity: $O(k)$ where k = number of classes implementing the protocol.
- Duck typing (`hasattr/getattr`): Shape-checking at *runtime, per call site*. Complexity: $\Omega(n)$ where n = number of call sites.

This explains why structural typing (TypeScript interfaces, Go interfaces, Python Protocols) is considered superior to duck typing in practice: both are shape-based, but structural typing performs the checking once at compile/definition time, while duck typing repeats the checking at every usage site.

Critical insight: Even though structural typing has better complexity than duck typing ($O(k)$ vs $\Omega(n)$), *both* are strictly dominated by nominal typing’s $O(1)$ error localization (Theorem 4.1). Nominal typing checks inheritance at the single class definition point--not once per implementing class (structural) or once per call site (duck).

2.2 The type() Theorem

Theorem 2.1 (Completeness). For any valid triple $(\text{name}, \text{bases}, \text{namespace})$, `type(name, bases, namespace)` produces a class C with exactly those properties.

Proof. By construction:

```
C = type(name, bases, namespace)
assert C.__name__ == name
assert C.__bases__ == bases
assert all(namespace[k] == getattr(C, k) for k in namespace)
```

The class statement is syntactic sugar for `type()`. Any class expressible via syntax is expressible via `type()`. ■

Theorem 2.2 (Semantic Minimality). The semantically minimal class constructor has arity 2: `type(bases, namespace)`.

Proof. - bases determines inheritance hierarchy and MRO - namespace determines attributes and methods - name is metadata; object identity distinguishes types at runtime - Each call to `type(bases, namespace)` produces a distinct object - Therefore name is not necessary for type semantics. ■

Theorem 2.3 (Practical Minimality). The practically minimal class constructor has arity 3: `type(name, bases, namespace)`.

Proof. The name string is required for: 1. Debugging: `repr(C) → <class '__main__.Foo'>` vs `<class '__main__.'???'>` 2. Serialization: Pickling uses `__name__`

to reconstruct classes 3. Error messages: “Expected Foo, got Bar” requires names 4. Metaclass protocols: `__init_subclass__`, registries key on `__name__`

Without name, the system is semantically complete but practically unusable. ■

Definition 2.6 (The Two-Axis Semantic Core). The semantic core of Python’s class system is: - bases: inheritance relationships (\rightarrow MRO, nominal typing) - namespace: attributes and methods (\rightarrow behavior, structural typing)

The name axis is orthogonal to both and carries no semantic weight.

Theorem 2.4 (Orthogonality of Semantic Axes). The bases and namespace axes are orthogonal.

Proof. Independence: - Changing bases does not change namespace content (only resolution order for inherited methods) - Changing namespace does not change bases or MRO

The factorization (bases, namespace) is unique. ■

Corollary 2.5. The semantic content of a class is fully determined by (bases, namespace). Two classes with identical bases and namespace are semantically equivalent, differing only in object identity.

2.3 C3 Linearization (Prior Work)

Theorem 2.6 (C3 Optimality). C3 linearization is the unique algorithm satisfying: 1. Monotonicity: If A precedes B in linearization of C, and C’ extends C, then A precedes B in linearization of C’ 2. Local precedence: A class precedes its parents in its own linearization 3. Consistency: Linearization respects all local precedence orderings

Proof. See Barrett et al. (1996), “A Monotonic Superclass Linearization for Dylan.” ■

Corollary 2.7. Given bases, MRO is deterministically derived. There is no configuration; there is only computation.

2.4 Abstract Class System Model

We formalize class systems independently of any specific language. This establishes that our theorems apply to any language with explicit inheritance, not just Python.

2.4.1 Axes (names as sugar) Definition 2.7 (Abstract Class System). A class system is a tuple (B, S) where: - B : Bases -- the set of explicitly declared parent types (inheritance) - S : Namespace -- the set of (attribute, value) pairs defining the type’s interface. Names are treated as syntactic sugar (aliases for structures already captured by S) and do not add observable power; we elide them henceforth.

Definition 2.8 (Class Constructor). A class constructor is a function:

$$\text{class} : N \times \mathcal{P}(T) \times S \rightarrow T$$

where T is the universe of types, taking a name, a set of base types, and a namespace, returning a new type.

Language instantiations:

Language	Name	Bases	Namespace	Constructor Syntax
Python	str	tuple[type]	dict[str, Any]	type(name, bases, namespace)
Java	String	Class<?>	method/field declarations	class Name extends Base { ... }
C#	string	Type	member declarations	class Name : Base { ... }
Ruby	Symbol	Class	method definitions	class Name < Base; end

Language	Name	Bases	Namespace	Constructor Syntax
TypeScript	string	Function	property declarations	class Name extends Base { ... }

Definition 2.9 (Reduced Class System). A class system is *reduced* if $B = \emptyset$ for all types (no inheritance). Examples: Go (structs only), C (no classes), JavaScript ES5 (prototype-based, no class keyword).

Remark (Implicit Root Classes). In Python, every class implicitly inherits from object: `class X: pass` has `X.__bases__ == (object,)`. Definition 2.9’s “ $B = \emptyset$ ” refers to the abstract model where inheritance from a universal root (Python’s object, Java’s Object) is elided. Equivalently, $B = \emptyset$ means “no user-declared inheritance beyond the implicit root.” The theorems apply when $B \neq \emptyset$ in this sense--i.e., when the programmer explicitly declares inheritance relationships.

Remark (Go Embedding \neq Inheritance). Go’s struct embedding provides method forwarding but is not inheritance: (1) embedded methods cannot be overridden--calling `outer.Method()` always invokes the embedded type’s implementation, (2) there is no MRO--Go has no linearization algorithm, (3) there is no `super()` equivalent. Embedding is composition with syntactic sugar, not polymorphic inheritance. Therefore Go has $B = \emptyset$.

2.4.2 Typing Disciplines as Axis Projections Definition 2.10 (Shape-Based Typing). A typing discipline is *shape-based* if type compatibility is determined solely by S (namespace):

$$\text{compatible}_{\text{shape}}(x, T) \iff S(\text{type}(x)) \supseteq S(T)$$

Shape-based typing projects out the B axis entirely. It cannot distinguish types with identical namespaces.

Remark (Operational Characterization). In Python, shape-based compatibility reduces to capability probing via `hasattr`: `all(hasattr(x, a) for a in S(T))`. We use `hasattr` (not `getattr`) because shape-based typing is about *capability detection*, not attribute retrieval. `getattr` involves metaprogramming machinery (`__getattr__`, `__getattribute__`, descriptors) orthogonal to type discipline.

Remark (Partial vs Full Structural Compatibility). Definition 2.10 uses partial compatibility (\supseteq): x has *at least* T ’s interface. Full compatibility ($=$) requires exact match. Both are $\{S\}$ -only disciplines; the capability gap (Theorem 2.17) applies to both. The distinction is a refinement *within* the S axis, not a fourth axis.

Definition 2.10a (Typing Discipline Completeness). A typing discipline is *complete* if it provides a well-defined, deterministic answer to “when is x compatible with T ?” for all x and declared T . Formally: there exists a predicate $\text{compatible}(x, T)$ that is well-defined for all (x, T) pairs where T is a declared type constraint.

Remark (Completeness vs Coherence). Definition 2.10a defines *completeness*: whether the discipline answers the compatibility question. Definition 8.3 later defines *coherence*: whether the discipline’s answers align with runtime semantics. These are distinct properties. A discipline can be complete but incoherent (TypeScript’s structural typing with class), or incomplete and thus trivially incoherent (duck typing).

Definition 2.10b (Structural Typing). Structural typing with declared interfaces (e.g., `typing.Protocol` [16, 35]) is coherent: T is declared as a Protocol with interface $S(T)$, and compatibility is $S(\text{type}(x)) \supseteq S(T)$. The discipline commits to a position: “structure determines compatibility.”

Definition 2.10c (Duck Typing). Duck typing is ad-hoc capability probing: `hasattr(x, attr)` [27] for individual attributes without declaring T . No interface is specified; the “required interface” is implicit in whichever attributes the code path happens to access.

Theorem 2.10d (Duck Typing Incoherence). Duck typing is not a coherent typing discipline.

Proof. A coherent discipline requires a well-defined $\text{compatible}(x, T)$ for declared T . Duck typing:

1. Does not declare T . There is no Protocol, no interface, no specification of required capabilities. The “interface” is implicit in the code.
2. Provides different answers based on code path. If module A probes $\text{hasattr}(x, \text{'foo'})$ and module B probes $\text{hasattr}(x, \text{'bar'})$, the same object x is “compatible” with A ’s requirements iff it has foo, and “compatible” with B ’s requirements iff it has bar. There is no unified T to check against.
3. Commits to neither position on structure-semantics relationship:
 - “Structure = semantics” would require checking *full* structural compatibility against a declared interface
 - “Structure \neq semantics” would require nominal identity via inheritance
 - Duck typing checks *partial* structure *ad-hoc* without declaration--neither position

A discipline that gives different compatibility answers depending on which code path executes, with no declared T to verify against, is not a discipline. It is the absence of one. ■

Related work (duck typing formalization). Refinement-based analyses and logics for dynamic languages approximate duck-typed behaviour statically (e.g., [10, 9]) and empirical interface extraction for dynamic checks has been explored [17]. These systems aim to prove safety for specific programs, not to define a globally coherent predicate $\text{compatible}(x, T)$ for undeclared T that is stable across code paths. Our incoherence result concerns that global typing-discipline property (Definition 8.3); it does not deny the usefulness of such analyses for individual programs.

Corollary 2.10e (Duck Typing vs Structural Typing). Duck typing ($\{S\}$, ad-hoc) is strictly weaker than structural typing with Protocols ($\{N, S\}$, declared). The distinction is not just “dominated” but “incoherent vs coherent.”

Proof. Protocols declare T , enabling static verification, documentation, and composition guarantees. Duck typing declares nothing. A Protocol-based discipline is coherent (Definition 2.10a); duck typing is not (Theorem 2.10d). ■

Corollary 2.10f (No Valid Context for Duck Typing). There exists no production context where duck typing is the correct choice.

Proof. In systems with inheritance ($B \neq \emptyset$): nominal typing ($\{N, B, S\}$) strictly dominates. In systems without inheritance ($B = \emptyset$): structural typing with Protocols ($\{N, S\}$) is coherent and strictly dominates incoherent duck typing. The only “advantage” of duck typing--avoiding interface declaration--is not a capability but deferred work with negative value (lost verification, documentation, composition guarantees). ■

Theorem 2.10g (Structural Typing Eliminability). In systems with inheritance ($B \neq \emptyset$), structural typing is eliminable via boundary adaptation.

Proof. Let S be a system using Protocol P to accept third-party type T that cannot be modified.

1. Adapter construction. Define adapter class: `class TAdapter(T, P_as_ABC): pass`
2. Boundary wrapping. At ingestion, wrap: `adapted = TAdapter(instance)` (for instances) or simply use `TAdapter` as the internal type (for classes)
3. Internal nominal typing. All internal code uses `isinstance(x, P_as_ABC)` with nominal semantics
4. Equivalence. The adapted system S' accepts exactly the same inputs as S but uses nominal typing internally

The systems are equivalent in capability. Structural typing provides no capability that nominal typing with adapters lacks. ■

Corollary 2.10h (Structural Typing as Convenience). When $B \neq \emptyset$, structural typing (Protocol) is not a typing necessity but a convenience--it avoids writing the 2-line adapter class. Convenience is not a typing capability.

Corollary 2.10i (Typing Discipline Hierarchy). The typing disciplines form a strict hierarchy:

1. Duck typing ($\{S\}$, ad-hoc): Incoherent (Theorem 2.10d). Never valid.
2. Structural typing ($\{N, S\}$, Protocol): Coherent but eliminable when $B \neq \emptyset$ (Theorem 2.10g). Valid only when $B = \emptyset$.
3. Nominal typing ($\{N, B, S\}$, ABC): Coherent and necessary. The only non-eliminable discipline for systems with inheritance.

Theorem 2.10j (Protocol Is Strictly Dominated When $B \neq \emptyset$). In systems with inheritance, Protocol is strictly dominated by explicit adapters.

Proof. Compare the two approaches for accepting third-party type T :

Property	Protocol	Explicit Adapter
Accepts same inputs	Yes	Yes
Documents adaptation boundary	No (implicit)	Yes (class definition)
Failure mode	Runtime (isinstance returns False, or missing method during execution)	Class definition time (if T lacks required methods)
Provenance	No (T not in your hierarchy)	Yes (adapter is in your hierarchy)
Explicit	No	Yes

The adapter provides strictly more: same inputs, plus explicit documentation, plus fail-loud at definition time, plus provenance. Protocol provides strictly less.

Protocol's only "advantage" is avoiding the 2-line adapter class. But avoiding explicitness is not an advantage--it is negative value. "Explicit is better than implicit" (Zen of Python, line 2). ■

Corollary 2.10k (Protocol's Value Proposition Is Negative). When $B \neq \emptyset$, Protocol trades explicitness, fail-loud behavior, and provenance for 2 fewer lines of code. Protocol's value proposition is negative.

Corollary 2.10k' (Protocol Is a Concession, Not an Alternative). When $B \neq \emptyset$, choosing Protocol is a *concession*--accepting reduced capabilities to defer adapter work. It is not an *alternative* because:

1. Protocol provides no capability that ABCs with adapters lack (Theorem 2.10j)
2. ABCs with adapters provide four capabilities Protocol lacks (provenance, identity, enumeration, conflict resolution)
3. The only "benefit" of Protocol is avoiding 2 lines of adapter code
4. Avoiding work is not a capability

An *alternative* implies comparable standing; a *concession* implies acknowledged inferiority for pragmatic expedience. Protocol is the latter. For Python systems where $B \neq \emptyset$, ABCs with adapters is the single non-concession choice.

Corollary 2.10l (Complete Typing Discipline Validity). The complete validity table:

Discipline	When $B \neq \emptyset$	When $B = \emptyset$
Duck typing	Never (incoherent)	Never (incoherent)
Protocol	Never (dominated by adapters)	Valid (only coherent option)
Nominal/Adapters	Always	N/A (requires B)

2.4.2a The Metaprogramming Capability Gap Beyond typing discipline, nominal and structural typing differ in a second, independent dimension: metaprogramming capability. This gap is not an implementation accident--it is mathematically necessary.

Definition 2.10m (Declaration-Time Event). A *declaration-time event* occurs when a type is defined, before any instance exists. Examples: class definition, inheritance declaration, trait implementation.

Definition 2.10n (Query-Time Check). A *query-time check* occurs when type compatibility is evaluated during program execution. Examples: `isinstance()`, Protocol conformance check, structural matching.

Definition 2.10o (Metaprogramming Hook). A *metaprogramming hook* is a user-defined function that executes in response to a declaration-time event. Examples: `__init_subclass__()`, `metaclass __new__()`, Rust's `#[derive]`.

Theorem 2.10p (Hooks Require Declarations). Metaprogramming hooks require declaration-time events. Structural typing provides no declaration-time events for conformance. Therefore, structural typing cannot provide conformance-based metaprogramming hooks.

Proof. 1. A hook is a function that fires when an event occurs. 2. In nominal typing, class `C(Base)` is a declaration-time event. The act of writing the inheritance declaration fires hooks: Python's `__init_subclass__()`, `metaclass __new__()`, Java's annotation processors, Rust's `derive` macros. 3. In structural typing, "Does X conform to interface I ?" is evaluated at query time. There is no syntax declaring " X implements I "--conformance is inferred from structure. 4. No declaration \rightarrow no event. No event \rightarrow no hook point. 5. Therefore, structural typing cannot provide hooks that fire when a type "becomes" conformant to an interface. ■

Theorem 2.10q (Enumeration Requires Registration). To enumerate all types conforming to interface I , a registry mapping types to interfaces is required. Nominal typing provides this registry implicitly via inheritance declarations. Structural typing does not.

Proof. 1. Enumeration requires a finite data structure containing conforming types. 2. In nominal typing, each declaration class `C(Base)` registers C as a subtype of `Base`. The transitive closure of declarations forms the registry. `__subclasses__()` queries this registry in $O(k)$ where $k = |\text{subtypes}(T)|$. 3. In structural typing, no registration occurs. Conformance is computed at query time by checking structural compatibility. 4. To enumerate conforming types under structural typing, one must iterate over all types in the universe and check conformance for each. In an open system (where new types can be added at any time), $|\text{universe}|$ is unbounded. 5. Therefore, enumeration under structural typing is $O(|\text{universe}|)$, which is infeasible for open systems. ■

Corollary 2.10r (Metaprogramming Capability Gap Is Necessary). The gap between nominal and structural typing in metaprogramming capability is not an implementation choice--it is a logical consequence of declaration vs. query.

Capability	Nominal Typing	Structural Typing	Why
Definition-time hooks	Yes (<code>__init_subclass__</code> , <code>metaclass</code>)	No	Requires declaration event
Enumerate implementers	Yes (<code>__subclasses__()</code> , $O(k)$)	No ($O(\infty)$ in open systems)	Requires registration

Capability	Nominal Typing	Structural Typing	Why
Auto-registration	Yes (metaclass <code>__new__</code>)	No	Requires hook
Derive/generate code	Yes (Rust <code>#[derive]</code> , Python descriptors)	No	Requires declaration context

Corollary 2.10s (Universal Applicability). This gap applies to all languages:

Language	Typing	Enumerate implementers?	Definition-time hooks?
Go	Structural	No	No
TypeScript	Structural	No	No (decorators are nominal--require class)
Python Protocol	Structural	No	No
Python ABC	Nominal	Yes (<code>__subclasses__()</code>)	Yes (<code>__init_subclass__</code> , metaclass)
Java	Nominal	Yes (reflection)	Yes (annotation processors)
C#	Nominal	Yes (reflection)	Yes (attributes, source generators)
Rust traits	Nominal (impl)	Yes	Yes (<code>#[derive]</code> , proc macros)
Haskell typeclasses	Nominal (instance)	Yes	Yes (deriving, TH)

Remark (TypeScript Decorators). TypeScript decorators appear to be metaprogramming hooks, but they attach to *class declarations*, not structural conformance. A decorator fires when class *C* is defined--this is a nominal event (the class is named and declared). Decorators cannot fire when “some object happens to match interface *I*”--that is a query, not a declaration.

Remark (The Two Axes of Dominance). Nominal typing strictly dominates structural typing on two independent axes: 1. Typing capability (Theorems 2.10j, 2.18): Provenance, identity, enumeration, conflict resolution 2. Metaprogramming capability (Theorems 2.10p, 2.10q): Hooks, registration, code generation

Neither axis is an implementation accident. Both follow from the structure of declaration vs. query. Protocol is dominated on both axes.

Remark. Languages without inheritance (Go) have $B = \emptyset$ by design. For these languages, structural typing with declared interfaces is the correct choice--not because structural typing is superior, but because nominal typing requires B and Go provides none. Go’s interfaces are coherent ($\{N, S\}$). Go does not use duck typing.

Remark (Historical Context). Duck typing became established in Python practice without formal capability analysis. This paper provides the first machine-verified comparison of typing discipline capabilities. See Appendix B for additional historical context.

Definition 2.11 (Nominal Typing). A typing discipline is *nominal* if type compatibility requires identity in the inheritance hierarchy:

$$\text{compatible}_{\text{nominal}}(x, T) \iff T \in \text{ancestors}(\text{type}(x))$$

where $\text{ancestors}(C) = \{C\} \cup \bigcup_{P \in B(C)} \text{ancestors}(P)$ (transitive closure over B).

2.4.3 Provenance as MRO Query Definition 2.12 (Provenance Query). A provenance query asks: “Given object x and attribute a , which type $T \in \text{MRO}(\text{type}(x))$ provided the value of a ?”

Theorem 2.13 (Provenance Requires MRO). Provenance queries require access to MRO, which requires access to B .

Proof. MRO is defined as a linearization over ancestors, which is the transitive closure over B . Without B , MRO is undefined. Without MRO, provenance queries cannot be answered. ■

Corollary 2.14 (Shape-Based Typing Cannot Provide Provenance). Shape-based typing cannot answer provenance queries.

Proof. By Definition 2.10, shape-based typing uses only S . By Theorem 2.13, provenance requires B . Shape-based typing has no access to B . Therefore shape-based typing cannot provide provenance. ■

Table 7: Cross-language instantiation of the (B, S) model

Language	N (Name)	B (Bases)	S (Namespace)	Type system
Python	<code>type(x).__name__</code>	<code>__bases__</code> ; <code>__mro__</code>	<code>__dict__</code> ; <code>dir()</code>	Nominal
Java	<code>getClass().getName()</code>	<code>getSuperclass()</code> , <code>getInterfaces()</code>	<code>getDeclaredMethods()</code>	Nominal
Ruby	<code>obj.class.name</code>	ancestors (or- dered)	methods, instance_variables	Nominal
C#	<code>GetType().Name</code>	<code>BaseType</code> , <code>GetInterfaces()</code>	<code>GetProperties()</code> , <code>GetMethods()</code>	Nominal

2.4.4 Cross-Language Instantiation All four languages provide runtime access to both axes (N is derivable from B). The critical difference lies in which axes the type system inspects.

Table 2.2: Generic Types Across Languages -- Parameterized N, Not a Fourth Axis

Language	Generics	Encoding	Runtime Behavior
Java	<code>List<T></code>	Parameterized N: (List, [T])	Erased to List
C#	<code>List<T></code>	Parameterized N: (List, [T])	Fully reified
TypeScript	<code>Array<T></code>	Parameterized N: (Array, [T])	Compile-time only
Rust	<code>Vec<T></code>	Parameterized N: (Vec, [T])	Monomorphized
Kotlin	<code>List<T></code>	Parameterized N: (List, [T])	Erased (reified via inline)
Swift	<code>Array<T></code>	Parameterized N: (Array, [T])	Specialized at compile-time
Scala	<code>List[T]</code>	Parameterized N: (List, [T])	Erased
C++	<code>vector<T></code>	Parameterized N: (vector, [T])	Template instantiation

Key observation: No major language invented a fourth axis for generics. All encode type parameters as an extension of the Name axis: $N_{\text{generic}} = (G, [T_1, \dots, T_k])$ where G is the

base name and $[T_i]$ are type arguments. The (B, S) model is universal across generic type systems.

2.5 The Axis Lattice Metatheorem

The two-axis model (B, S) induces a lattice of typing disciplines. Each discipline is characterized by which axes it inspects:

Axis Subset	Discipline	Example
\emptyset	Untyped	Accept all
$\{N\}$	Named-only	Type aliases
$\{S\}$	Shape-based (ad-hoc)	Duck typing, <code>hasattr</code>
$\{S\}$	Shape-based (declared)	OCaml <code>< get : int; .. ></code>
$\{N, S\}$	Named structural	<code>typing.Protocol</code>
$\{N, B, S\}$	Nominal	ABCs, <code>isinstance</code>

Critical distinction within $\{S\}$: The axis subset does not capture whether the interface is *declared*. This is orthogonal to which axes are inspected:

Discipline	Axes Used	Interface Declared?	Coherent?
Duck typing	$\{S\}$	No (ad-hoc <code>hasattr</code>)	No (Thm 2.10d)
OCaml structural	$\{S\}$	Yes (inline type)	Yes
Protocol	$\{N, S\}$	Yes (named interface)	Yes
Nominal	$\{N, B, S\}$	Yes (class hierarchy)	Yes

Duck typing and OCaml structural typing both use $\{S\}$, but duck typing has no declared interface--conformance is checked ad-hoc at runtime via `hasattr`. OCaml declares the interface inline: `< get : int; set : int -> unit >` is a complete type specification, statically verified. The interface's "name" is its canonical structure: $N = \text{canonical}(S)$.

Theorem 2.10d (Incoherence) applies to duck typing, not to OCaml. The incoherence arises from the lack of a declared interface, not from using axis subset $\{S\}$.

Theorems 2.10p-q (Metaprogramming Gap) apply to both. Neither duck typing nor OCaml structural typing can enumerate conforming types or provide definition-time hooks, because neither has a declaration event. This is independent of coherence.

Note: `hasattr(obj, 'foo')` checks namespace membership, not `type(obj).__name__`. `typing.Protocol` uses $\{N, S\}$: it can see type names and namespaces, but ignores inheritance. Our provenance impossibility theorems use the weaker $\{N, S\}$ constraint to prove stronger results.

Theorem 2.15 (Axis Lattice Dominance). For any axis subsets $A \subseteq A' \subseteq \{N, B, S\}$, the capabilities of discipline using A are a subset of capabilities of discipline using A' :

$$\text{capabilities}(A) \subseteq \text{capabilities}(A')$$

Proof. Each axis enables specific capabilities: - N : Type naming, aliasing - B : Provenance, identity, enumeration, conflict resolution - S : Interface checking

A discipline using subset A can only employ capabilities enabled by axes in A . Adding an axis to A adds capabilities but removes none. Therefore the capability sets form a monotonic lattice under subset inclusion. ■

Corollary 2.16 (Bases Axis Primacy). The Bases axis B is the source of all strict dominance. Specifically: provenance, type identity, subtype enumeration, and conflict resolution all require B . Any discipline that discards B forecloses these capabilities.

Theorem 2.17 (Capability Completeness). The capability set \mathcal{C}_B = {provenance, identity, enumeration, conflict resolution} is exactly the set of capabilities enabled by the Bases axis. Formally:

$$c \in \mathcal{C}_B \iff c \text{ requires } B$$

Proof. We prove both directions:

(\Rightarrow) Each capability in \mathcal{C}_B requires B :

1. Provenance (“which type provided value v ?”): By Definition 2.12, provenance queries require MRO traversal. MRO is the C3 linearization of ancestors, which is the transitive closure over B . Without B , MRO is undefined. ✓
2. Identity (“is x an instance of T ?”): By Definition 2.11, nominal compatibility requires $T \in \text{ancestors}(\text{type}(x))$. Ancestors is defined as transitive closure over B . Without B , ancestors is undefined. ✓
3. Enumeration (“what are all subtypes of T ?”): A subtype S of T satisfies $T \in \text{ancestors}(S)$. Enumerating subtypes requires inverting the ancestor relation, which requires B . ✓
4. Conflict resolution (“which definition wins in diamond inheritance?”): Diamond inheritance produces multiple paths to a common ancestor. Resolution uses MRO ordering, which requires B . ✓

(\Leftarrow) No other capability requires B :

We exhaustively enumerate capabilities NOT in \mathcal{C}_B and show none require B :

5. Interface checking (“does x have method m ?”): Answered by inspecting $S(\text{type}(x))$. Requires only S . Does not require B . ✓
6. Type naming (“what is the name of type T ?”): Answered by inspecting $N(T)$. Requires only N . Does not require B . ✓
7. Value access (“what is $x.a$?”): Answered by attribute lookup in $S(\text{type}(x))$. Requires only S . Does not require B . ✓

Remark (Inherited Attributes). For inherited attributes, $S(\text{type}(x))$ means the *effective* namespace including inherited members. Computing this effective namespace initially requires B (to walk the MRO), but once computed, accessing a value from the flattened namespace requires only S . The distinction is between *computing* the namespace (requires B) and *querying* a computed namespace (requires only S). Value access is the latter.

8. Method invocation (“call $x.m()$ ”): Answered by retrieving m from S and invoking. Requires only S . Does not require B . ✓

No capability outside \mathcal{C}_B requires B . Therefore \mathcal{C}_B is exactly the B -dependent capabilities. ■

Significance: This is a tight characterization, not an observation. The capability gap is not “here are some things you lose”—it is “here is exactly what you lose, nothing more, nothing less.” This completeness result is what distinguishes a formal theory from an enumerated list.

Theorem 2.18 (Strict Dominance -- Abstract). In any class system with $B \neq \emptyset$, nominal typing strictly dominates shape-based typing.

Proof. Let $\mathcal{C}_{\text{shape}}$ = capabilities of shape-based typing. Let $\mathcal{C}_{\text{nominal}}$ = capabilities of nominal typing.

Shape-based typing can check interface satisfaction: $S(\text{type}(x)) \supseteq S(T)$.

Nominal typing can: 1. Check interface satisfaction (equivalent to shape-based)

2. Check type identity: $T \in \text{ancestors}(\text{type}(x))$ -- impossible for shape-based 3.

Answer provenance queries -- impossible for shape-based (Corollary 2.14) 4. Enumerate subtypes -- impossible for shape-based 5. Use type as dictionary key -- impossible for shape-based

Therefore $C_{\text{shape}} \subset C_{\text{nominal}}$ (strict subset). In a class system with $B \neq \emptyset$, both disciplines are available. Choosing shape-based typing forecloses capabilities for zero benefit. ■

2.5.1 The Decision Procedure

Given a language L and development context C :

```
FUNCTION select_typing_discipline(L, C):
  IF L has no inheritance syntax (B = {}):
    RETURN structural # Theorem 3.1: correct when B absent

  # For all cases where B != {}:
  RETURN nominal # Theorem 2.18: strict dominance

  # Note: "retrofit" is not a separate case. When integrating
  # external types, use explicit adapters (Theorem 2.10j).
  # Protocol is a convenience, not a correct discipline.
```

This is a decision procedure, not a preference. The output is determined by whether $B = \emptyset$.

3 Universal Dominance

Thought experiment: What if `type()` only took namespace?

Given that the semantic core is (bases, namespace), what if we further reduce to just namespace?

```
\# Hypothetical minimal class constructor
def type\_minimal(namespace: dict) {-\textgreater{}} type:
  """Create a class from namespace only."""
  return type("", (), namespace)
```

Definition 3.1 (Namespace-Only System). A namespace-only class system is one where:
- Classes are characterized entirely by their namespace (attributes/methods) - No explicit inheritance mechanism exists (bases axis absent)

Theorem 3.1 (Structural Typing Is Correct for Namespace-Only Systems).

In a namespace-only system, structural typing is the unique correct typing discipline.

Proof. 1. Let A and B be classes in a namespace-only system 2. $A \equiv B$ iff $\text{namespace}(A) = \text{namespace}(B)$ (by definition of namespace-only) 3. Structural typing checks: $\text{namespace}(x) \supseteq \text{signature}(T)$ 4. This is the only information available for type checking 5. Therefore structural typing is correct and complete. ■

Corollary 3.2 (Go's Design Is Consistent). Go has no inheritance. Interfaces are method sets. Structural typing is correct for Go.

Corollary 3.3 (TypeScript's Static Type System). TypeScript's *static* type system is structural. Class compatibility is determined by shape, not inheritance. However, at runtime, JavaScript's prototype chain provides nominal identity (`instanceof` checks the chain) [22]. This creates a coherence tension discussed in Section 8.7.

The Critical Observation (Semantic Axes):

System	Semantic Axes	Correct Discipline
Namespace-only	(namespace)	Structural
Full Python	(bases, namespace)	Nominal

The name axis is metadata in both cases. It doesn't affect which typing discipline is correct and is treated as syntactic sugar hereafter.

Binder vs. Observable Identity. In *pure* structural typing, “name” is only a binder/alias for a shape; it is not an observable discriminator. Conformance depends solely on namespace (structure). Any observable discriminator (brand/tag/nominal identity) is an added axis: once it is observable to the conformance relation, the discipline is no longer purely structural.

Lineage axis = ordered identities. The Bases axis B can be viewed as the ordered lineage $\text{MRO}(T)$ (C3 linearization). The “identity” capability is a projection of this lineage: $\text{head}(\text{MRO}(T)) = T$ (exact type), and instance-of is membership $U \in \text{MRO}(T)$. Provenance and conflict resolution are the other projections. There is no separate “I axis”; identity is one of the queries made available by B . A discipline that can only test $\text{head}(\text{MRO}(T))$ has tag identity but not inheritance capabilities—it is a strict subset of full B .

Theorem 3.4 (Nominal Typing Pareto-Dominance). When a bases axis exists in the class system, nominal typing Pareto-dominates all shape-based alternatives (provides strictly more capabilities with zero additional cost). This dominance is universal, not limited to greenfield development.

Proof. We prove this in two steps: (1) strict dominance holds unconditionally, (2) retrofit constraints do not constitute an exception.

Step 1: Strict Dominance is Unconditional.

Let D_{shape} be any shape-based discipline (uses only $\{S\}$). Let D_{nominal} be nominal typing (uses $\{B, S\}$; names are aliases).

By Theorem 2.15 (Axis Lattice Dominance):

$$\text{capabilities}(D_{\text{shape}}) \subseteq \text{capabilities}(D_{\text{nominal}})$$

By Theorem 2.17 (Capability Completeness), D_{nominal} provides four capabilities that D_{shape} cannot: provenance, identity, enumeration, conflict resolution.

Therefore: $\text{capabilities}(D_{\text{shape}}) \subset \text{capabilities}(D_{\text{nominal}})$ (strict subset).

This dominance holds regardless of whether the system currently uses these capabilities. The capability gap exists by the structure of axis subsets, not by application requirements.

Step 2: Retrofit Constraints Do Not Constitute an Exception.

One might object: “In retrofit contexts, external types cannot be made to inherit from my ABCs, so nominal typing is unavailable.”

This objection was addressed in Theorem 2.10j (Protocol Dominated by Adapters): when $B \neq \emptyset$, nominal typing with adapters provides all capabilities of Protocol plus four additional capabilities. The “retrofit exception” is not an exception. Adapters are the mechanism that makes nominal typing universally available.

- External type cannot inherit from your ABC? Wrap it in an adapter that does.
- Protocol avoids the adapter? Yes, but avoiding adapters is a convenience, not a capability (Corollary 2.10k).

Conclusion: Shape-Based Typing Has Negative Expected Value.

Given two available options A and B where $\text{capabilities}(A) \subset \text{capabilities}(B)$ and $\text{cost}(A) = \text{cost}(B)$, choosing A is Pareto-dominated: there exists no rational justification for A over B under expected utility maximization.

When $B \neq \emptyset$:

- D_{shape} is Pareto-dominated by D_{nominal}
- Same mental load: `isinstance()` API identical for both
- Foreclosure is permanent: Missing capabilities cannot be added later (Theorem 3.67)
- Ignorant choice has expected cost: $E[\text{gap}] > 0$ (Theorem 3.68)
- Retrofit cost dominates analysis cost: $\text{cost}_{\text{retrofit}} > \text{cost}_{\text{analysis}}$ (Theorem 3.69)
- Analysis has positive expected value: $E[V_{\text{analysis}}] > 0$ (Theorem 3.70)

Therefore: Choosing shape-based typing when inheritance exists has negative expected value under capability-based utility.

Note on “what if I don’t need the extra capabilities?”

This objection misunderstands option value. A Pareto-dominated choice has negative expected value even if the additional capabilities are never exercised:

1. Capability availability has zero marginal cost (identical `isinstance()` syntax)
2. Future requirements are uncertain; capability foreclosure has negative option value (Theorem 3.70)
3. Capability gaps are irreversible: cannot transition from shape to nominal without discipline rewrite (Theorem 3.67)
4. Architecture choices have persistent effects; one-time decisions determine long-term capability sets

The bases axis creates an information asymmetry: nominal typing can access inheritance structure; shape-based typing cannot. Adapters ensure nominal typing is universally available.

Theorem 3.71 (Unique Optimum): Under capability-based utility maximization, nominal typing is the unique optimal choice when $B \neq \emptyset$. Choosing shape-based typing while maximizing capabilities contradicts the stated objective (Theorem 3.72: proven incoherence). ■

Theorem 3.5 (Strict Dominance, Universal). Nominal typing strictly dominates shape-based typing whenever $B \neq \emptyset$: nominal provides all capabilities of shape-based typing plus additional capabilities, at equal or lower cost.

Proof. Consider Python’s concrete implementations: - Shape-based: `typing.Protocol` (structural typing) - Nominal: Abstract Base Classes (ABCs)

Let S = capabilities provided by Protocol, N = capabilities provided by ABCs.

What Protocols provide: 1. Interface enforcement via method signature matching 2. Type checking at static analysis time (mypy, pyright) 3. No runtime `isinstance()` check (by default)

What ABCs provide: 1. Interface enforcement via `@abstractmethod` (equivalent to Protocol) 2. Type checking at static analysis time (equivalent to Protocol) 3. Type identity via `isinstance()` (Protocol cannot provide this) 4. Provenance tracking via MRO position (Protocol cannot provide this) 5. Exhaustive enumeration via `__subclasses__()` (Protocol cannot provide this) 6. Type-as-dictionary-key via `type()` identity (Protocol cannot provide this) 7. Runtime enforcement at instantiation (Protocol only checks statically)

Therefore $S \subset N$ (strict subset). Both require explicit type declarations. The declaration cost is equivalent: one class definition per interface. Therefore, nominal typing provides strictly more capabilities at equal or lower cost (earlier failure). ■

Corollary 3.6 (Shape Typing Incorrectness). When $B \neq \emptyset$, using shape-based typing instead of nominal typing is not suboptimal: it is incorrect.

Proof. By Theorem 3.5, nominal typing strictly dominates shape-based typing. By Theorem 2.10j, adapters make nominal typing universally available. Choosing a strictly dominated option when the superior option is available is definitionally incorrect. ■

3.1 The Absolute Claim

Claim (Typing Discipline Correctness). In any programming language with explicit inheritance syntax ($B \neq \emptyset$), shape-based typing (structural typing, Protocol-based typing) is incorrect. Duck typing is incoherent (Theorem 2.10d). It is not even a valid typing discipline. Nominal typing is correct. This is not a preference, recommendation, or tradeoff. It is a mathematical fact derivable from the structure of class systems.

Proof. By Theorem 2.18 (Strict Dominance), nominal typing provides all capabilities of shape-based typing plus additional capabilities (provenance, type identity, subtype enumeration, type-as-key). By Theorem 2.10j, adapters eliminate the retrofit exception. Therefore, choosing shape-based typing when $B \neq \emptyset$ is choosing the strictly dominated option. ■

What “incorrect” means: 1. Information-theoretic: Shape-based typing discards the B axis. Discarding available information without compensating benefit is suboptimal by definition. 2. Capability-theoretic: Shape-based typing forecloses capabilities that nominal typing provides. Foreclosing capabilities for zero benefit is incorrect. 3. Decision-theoretic: Given the choice between two options where one strictly dominates, choosing the dominated option is irrational.

3.2 Information-Theoretic Foundations

This section establishes the formal foundation of our results. We prove three theorems that make claims about all possible typing disciplines, not just our particular model.

3.8.1 The Impossibility Theorem Definition 3.10 (Typing Discipline). A *typing discipline* \mathcal{D} over axis set $A \subseteq \{N, B, S\}$ is a collection of computable functions that take as input only the projections of types onto axes in A .

Definition 3.11 (Shape Discipline -- Theoretical Upper Bound). A *shape discipline* is a typing discipline over $\{N, S\}$. It has access to type names and namespaces, but not to the Bases axis.

Note: Definition 2.10 defines practical shape-based typing as using only $\{S\}$ (duck typing doesn’t inspect names). We use the weaker $\{N, S\}$ constraint here to prove a stronger impossibility result: even if a discipline has access to type names, it STILL cannot compute provenance without B . This generalizes to all shape-based systems, including hypothetical ones that inspect names.

Definition 3.12 (Provenance Function). The *provenance function* is:

$$\text{prov} : \text{Type} \times \text{Attr} \rightarrow \text{Type}$$

where $\text{prov}(T, a)$ returns the type in T ’s MRO that provides attribute a .

Theorem 3.13 (Provenance Impossibility -- Universal). Let \mathcal{D} be ANY shape discipline (typing discipline over $\{N, S\}$ only). Then \mathcal{D} cannot compute prov .

Proof. We prove this by showing that prov requires information that is information-theoretically absent from (S) .

1. Information content of (S) . A shape discipline receives: the type name $N(T)$ and the namespace $S(T) = \{a_1, a_2, \dots, a_k\}$ (the set of attributes T declares or inherits).
2. Information content required by prov . The function $\text{prov}(T, a)$ must return *which ancestor type* originally declared a . This requires knowing the MRO of T and which position in the MRO declares a .
3. MRO is defined exclusively by B . By Definition 2.11, $\text{MRO}(T) = \text{C3}(T, B(T))$. The C3 linearization of T ’s base classes. The function $B : \text{Type} \rightarrow \text{List}[\text{Type}]$ is the Bases axis.

4. (S) contains no information about B . The namespace $S(T)$ is the *union* of attributes from all ancestors. It does not record *which* ancestor contributed each attribute. Two types with identical S can have completely different B (and therefore different MROs and different provenance answers).

5. Concrete counterexample. Let:

- $A = \text{type}("A", (), \{ "x" : 1 \})$
- $B_1 = \text{type}("B1", (A,), \{ \})$
- $B_2 = \text{type}("B2", (), \{ "x" : 1 \})$

Then $S(B_1) = S(B_2) = \{ "x" \}$ (both have attribute “x”), but:

- $\text{prov}(B_1, "x") = A$ (inherited from parent)
- $\text{prov}(B_2, "x") = B_2$ (declared locally)

A shape discipline cannot distinguish B_1 from B_2 , therefore cannot compute prov. ■

Corollary 3.14 (No Algorithm Exists). There exists no algorithm, heuristic, or approximation that allows a shape discipline to compute provenance. This is not a limitation of current implementations: it is information-theoretically impossible.

Proof. The proof of Theorem 3.13 shows that the input (S) contains strictly less information than required to determine prov. No computation can extract information that is not present in its input. ■

Significance: This is not “our model doesn’t have provenance.” It is “NO model over (S) can have provenance.” The impossibility is mathematical, not implementational.

3.8.2 The Derived Characterization Theorem A potential objection is that our capability enumeration $\mathcal{C}_B = \{\text{provenance, identity, enumeration, conflict resolution}\}$ is arbitrary. We now prove it is derived from information structure, not chosen.

Definition 3.15 (Query). A *query* is a computable function $q : \text{Type}^k \rightarrow \text{Result}$ that a typing discipline evaluates.

Definition 3.16 (Shape-Respecting Query). A query q is *shape-respecting* if for all types with $S(A) = S(B)$:

$$q(\dots, A, \dots) = q(\dots, B, \dots)$$

That is, shape-equivalent types produce identical query results.

Definition 3.17 (B-Dependent Query). A query q is *B-dependent* if there exist types A, B with $S(A) = S(B)$ but $q(A) \neq q(B)$.

Theorem 3.18 (Query Space Partition). Every query is either shape-respecting or B-dependent. These categories are mutually exclusive and exhaustive.

Proof. - *Mutual exclusion:* If q is shape-respecting, then $S(A) = S(B) \Rightarrow q(A) = q(B)$. If q is B-dependent, then $\exists A, B : S(A) = S(B) \wedge q(A) \neq q(B)$. These are logical negations. - *Exhaustiveness:* For any query q , either $\forall A, B : S(A) = S(B) \Rightarrow q(A) = q(B)$ (shape-respecting) or $\exists A, B : S(A) = S(B) \wedge q(A) \neq q(B)$ (B-dependent). Tertium non datur. ■

Theorem 3.19 (Capability Gap = B-Dependent Queries). The capability gap between shape and nominal typing is EXACTLY the set of B-dependent queries:

$$\text{NominalCapabilities} \setminus \text{ShapeCapabilities} = \{q : q \text{ is B-dependent}\}$$

Proof. - (\supseteq) If q is B-dependent, then $\exists A, B$ with $S(A) = S(B)$ but $q(A) \neq q(B)$. Shape disciplines cannot distinguish A from B , so cannot compute q . Nominal disciplines have access to B , so can distinguish A from B via MRO. Therefore q is in the gap.
- (\subseteq) If q is in the gap, then nominal can compute it but shape cannot. If q were

shape-respecting, shape could compute it (contradiction). Therefore q is B-dependent. ■

Theorem 3.20 (Four Capabilities Are Complete). The set \mathcal{C}_B = {provenance, identity, enumeration, conflict resolution} is the complete set of B-dependent query classes.

Proof. We show that every B-dependent query reduces to one of these four:

1. Provenance queries (“which type provided a ?”): Any query requiring ancestor attribution.
2. Identity queries (“is x an instance of T ?”): Any query requiring MRO membership.
3. Enumeration queries (“what are all subtypes of T ?”): Any query requiring inverse MRO.
4. Conflict resolution queries (“which definition wins?”): Any query requiring MRO ordering.

Completeness argument: A B-dependent query must use information from B . The only information in B is: - Which types are ancestors (enables identity, provenance) - The order of ancestors (enables conflict resolution) - The inverse relation (enables enumeration)

These three pieces of information (ancestor set, ancestor order, inverse relation) generate exactly four query classes. No other information exists in B . ■

Corollary 3.21 (Capability Set Is Minimal). $|\mathcal{C}_B| = 4$ and no element is redundant.

Proof. Each capability addresses a distinct aspect of B : - Provenance: forward lookup by attribute - Identity: forward lookup by type - Enumeration: inverse lookup - Conflict resolution: ordering

Removing any one leaves queries that the remaining three cannot answer. ■

3.8.3 The Complexity Lower Bound Theorem Our $O(1)$ vs $\Omega(n)$ complexity claim requires proving that $\Omega(n)$ is a lower bound, not merely an upper bound. We must show that NO algorithm can do better.

Definition 3.22 (Computational Model). We formalize error localization as a decision problem in the following model:

- Input: A program P with n call sites c_1, \dots, c_n , each potentially accessing attribute a on objects of type T .
- Oracle: The algorithm may query an oracle $\mathcal{O}(c_i) \in \{\text{uses } a, \text{does not use } a\}$ for each call site.
- Output: The set $V \subseteq \{c_1, \dots, c_n\}$ of call sites that access a on objects lacking a .
- Correctness: The algorithm must output the exact set V for all valid inputs.

This model captures duck typing’s fundamental constraint: type compatibility is checked at each call site, not at declaration.

Definition 3.23 (Inspection Cost). The *cost* of an algorithm is the number of oracle queries in the worst case over all inputs.

Theorem 3.24 (Duck Typing Lower Bound). Any algorithm that correctly solves error localization in the above model requires $\Omega(n)$ oracle queries in the worst case.

Proof. By adversary argument and information-theoretic counting.

1. Adversary construction. Fix any deterministic algorithm \mathcal{A} . We construct an adversary that forces \mathcal{A} to query at least $n - 1$ call sites.
2. Adversary strategy. The adversary maintains a set S of “candidate violators”--call sites that could be the unique violating site. Initially $S = \{c_1, \dots, c_n\}$. When \mathcal{A} queries $\mathcal{O}(c_i)$:

- If $|S| > 1$: Answer “does not use a ” and set $S \leftarrow S \setminus \{c_i\}$

- If $|S| = 1$: Answer consistently with $c_i \in S$ or $c_i \notin S$
3. Lower bound derivation. The algorithm must distinguish between n possible inputs (exactly one of c_1, \dots, c_n violates). Each query eliminates at most one candidate. After $k < n - 1$ queries, $|S| \geq 2$, so the algorithm cannot determine the unique violator. Therefore \mathcal{A} requires at least $n - 1 \in \Omega(n)$ queries.
 4. Generalization. For the case where multiple call sites may violate: there are 2^n possible subsets. Each binary query provides at most 1 bit. Therefore $\log_2(2^n) = n$ queries are necessary to identify the exact subset. ■

Remark (Static Analysis). Static analyzers precompute call site information via control-flow analysis over the program text. This shifts the $\Omega(n)$ cost to analysis time rather than eliminating it. The bound characterizes the inherent information content required-- n bits to identify n potential violation sites--regardless of when that information is gathered.

Theorem 3.25 (Nominal Typing Upper Bound). Nominal error localization requires exactly 1 inspection.

Proof. In nominal typing, constraints are declared at the class definition. The constraint “type T must have attribute a ” is checked at the single location where T is defined. If the constraint is violated, the error is at that location. No call site inspection is required. ■

Corollary 3.26 (Complexity Gap Is Unbounded). The ratio $\frac{\text{DuckCost}(n)}{\text{NominalCost}}$ grows without bound:

$$\lim_{n \rightarrow \infty} \frac{\Omega(n)}{O(1)} = \infty$$

Proof. Immediate from Theorems 3.24 and 3.25. ■

Corollary 3.27 (Lower Bound Is Tight). The $\Omega(n)$ lower bound for duck typing is achieved by naive inspection--no algorithm can do better, and simple algorithms achieve this bound.

Proof. Theorem 3.24 proves $\Omega(n)$ is necessary. Linear scan of call sites achieves $O(n)$. Therefore the bound is tight. ■

3.3 Summary: Core Formal Results

We have established three theorems with universal scope:

Theorem	Statement	Proof Technique
3.13 (Impossibility)	No shape discipline can compute provenance	Information-theoretic: input lacks required data
3.19 (Derived Characterization)	Capability gap = B-dependent queries	Mathematical: query space partitions exactly
3.24 (Lower Bound)	Duck typing requires $\Omega(n)$ inspections	Adversary argument: any algorithm can be forced

These are not claims about our model--they are claims about the universe of possible typing systems. The theorems establish:

- Theorem 3.13 proves no model over (S) can provide provenance.
- Theorem 3.19 proves the capability enumeration is derived from information structure.
- Theorem 3.24 proves no algorithm can overcome the information-theoretic limitation.

These results follow from the structure of the problem, not from our particular formalization.

3.4 Information-Theoretic Completeness

For completeness, we restate the original characterization in the context of the new foundations.

Definition 3.28 (Query). A *query* is a predicate $q : \text{Type} \rightarrow \text{Bool}$ that a typing discipline can evaluate.

Definition 3.29 (Shape-Respecting Query). A query q is *shape-respecting* if for all types A, B with $S(A) = S(B)$:

$$q(A) = q(B)$$

That is, shape-equivalent types cannot be distinguished by q .

Theorem 3.30 (Capability Gap Characterization). Let `ShapeQueries` be the set of all shape-respecting queries, and let `AllQueries` be the set of all queries. If there exist types $A \neq B$ with $S(A) = S(B)$, then:

$$\text{ShapeQueries} \subsetneq \text{AllQueries}$$

Proof. The identity query $\text{isA}(T) := (T = A)$ is in `AllQueries` but not `ShapeQueries`, because $\text{isA}(A) = \text{true}$ but $\text{isA}(B) = \text{false}$ despite $S(A) = S(B)$. ■

Corollary 3.31 (Derived Capability Set). The capability gap between shape-based and nominal typing is exactly the set of queries that depend on the Bases axis:

$$\text{Capability Gap} = \{q \mid \exists A, B. S(A) = S(B) \wedge q(A) \neq q(B)\}$$

This is not an enumeration--it's a characterization. Our listed capabilities (provenance, identity, enumeration, conflict resolution) are instances of this set, not arbitrary choices.

Information-Theoretic Interpretation: Information theory tells us that discarding information removes the ability to answer queries that depend on that information. The Bases axis contains information about inheritance relationships. Shape-based typing discards this axis. Therefore, any query that depends on inheritance--provenance, identity, enumeration, conflict resolution--cannot be answered. This follows from the structure of the information available.

3.5 Completeness and Robustness Theorems

This section presents additional theorems that establish the completeness and robustness of our results. Each theorem addresses a specific aspect of the model's coverage.

3.11.1 Model Completeness Theorem 3.32 (Model Completeness). The (B, S) model captures all information constitutive of a type. Any computable function over types is expressible as a function of (B, S) .

Proof. The proof proceeds by constitutive definition, not empirical enumeration.

In Python, `type(name, bases, namespace)` is the universal type constructor. Every type T is created by some invocation `type(n, b, s)`--either explicitly or via the `class` statement (which is syntactic sugar for `type()`). A type does not merely *have* (B, S) ; a type *is* (B, S) . There is no other information constitutive of a type object.

Therefore, for any computable function $g : \text{Type} \rightarrow \alpha$:

$$g(T) = g(\text{type}(n, b, s)) = h(n, b, s)$$

for some computable h . Any function of a type is definitionally a function of the triple that constitutes it.

Remark (Derived vs. Constitutive). Properties like `__mro__` (method resolution order) or `__module__` are not counterexamples: MRO is computed from B by C3 linearization; `__module__` is stored in the namespace S . These are *derived from* or *contained in* (B, S) , not independent of it.

This is a definitional closure: a critic cannot exhibit a “fourth axis” because any proposed axis is either (a) stored in S , (b) computable from (B, S) , or (c) not part of the type’s semantic identity (e.g., memory address). ■

Corollary 3.33 (No Hidden Information). There exists no “fourth axis” that shape-based typing could use to recover provenance. The information is structurally absent—not because we failed to model it, but because types *are* (B, S) by construction.

3.11.2 Capability Comparison Theorem 3.34 (Capability Superset). Let $\mathcal{C}_{\text{duck}}$ be the capabilities available under duck typing. Let \mathcal{C}_{nom} be the capabilities under nominal typing. Then:

$$\mathcal{C}_{\text{duck}} \subseteq \mathcal{C}_{\text{nom}}$$

Proof. Duck typing operations are: 1. Attribute access: `getattr(obj, "name")` 2. Attribute existence: `hasattr(obj, "name")` 3. Method invocation: `obj.method()`

All three operations are available in nominal systems. Nominal typing adds type identity operations; it does not remove duck typing operations. ■

Theorem 3.35 (Strict Superset). The inclusion is strict:

$$\mathcal{C}_{\text{duck}} \subsetneq \mathcal{C}_{\text{nom}}$$

Proof. Nominal typing provides provenance, identity, enumeration, and conflict resolution (Theorem 2.17). Duck typing cannot provide these (Theorem 3.13). Therefore:

$$\mathcal{C}_{\text{nom}} = \mathcal{C}_{\text{duck}} \cup \mathcal{C}_B$$

where $\mathcal{C}_B \neq \emptyset$. ■

Corollary 3.36 (No Capability Tradeoff). Choosing nominal typing over duck typing: - Forecloses zero capabilities - Gains four capabilities

There is no capability tradeoff. Nominal typing strictly dominates.

Remark (Capability vs. Code Compatibility). The capability superset does not mean “all duck-typed code runs unchanged under nominal typing.” It means “every operation expressible in duck typing is expressible in nominal typing.” The critical distinction:

- False equivalence (duck typing): `WellFilterConfig` and `StepWellFilterConfig` are structurally identical but semantically distinct (different MRO positions, different scopes). Duck typing conflates them—it literally cannot answer “which type is this?” This is not flexibility; it is information destruction.
- Type distinction (nominal typing): `isinstance(config, StepWellFilterConfig)` distinguishes them in $O(1)$. The distinction is expressible because nominal typing preserves type identity.

Duck typing’s “acceptance” of structurally-equivalent types is not a capability—it is the *absence* of the capability to distinguish them. Nominal typing adds this capability without removing any duck typing operation. See Case Study 1 (§5.2, Theorem 5.1) for the complete production example demonstrating that structural identity \neq semantic identity.

3.11.3 Axiom Justification Lemma 3.37 (Shape Axiom is Definitional). The axiom “shape-based typing treats same-namespace types identically” is not an assumption--it is the definition of shape-based typing.

Proof. Shape-based typing is defined as a typing discipline over $\{S\}$ only (Definition 2.10). If a discipline uses information from B (the Bases axis) to distinguish types, it is, by definition, not shape-based.

The axiom is not: “We assume shape typing can’t distinguish same-shape types.” The axiom is: “Shape typing means treating same-shape types identically.”

Any system that distinguishes same-shape types is using B (explicitly or implicitly).

■

Corollary 3.38 (No Clever Shape System). There exists no “clever” shape-based system that can distinguish types A and B with $S(A) = S(B)$. Such a system would, by definition, not be shape-based.

3.11.4 Extension Impossibility Theorem 3.39 (Extension Impossibility). Let \mathcal{D} be any duck typing system. Let \mathcal{D}' be \mathcal{D} extended with any computable function $f : \text{Namespace} \rightarrow \alpha$. Then \mathcal{D}' still cannot compute provenance.

Proof. Provenance requires distinguishing types A and B where $S(A) = S(B)$ but $\text{prov}(A, a) \neq \text{prov}(B, a)$ for some attribute a .

Any function $f : \text{Namespace} \rightarrow \alpha$ maps A and B to the same value, since $S(A) = S(B)$ implies f receives identical input for both.

Therefore, f provides no distinguishing information. The only way to distinguish A from B is to use information not in Namespace--i.e., the Bases axis B .

No computable extension over $\{N, S\}$ alone can recover provenance. ■

Corollary 3.40 (No Future Fix). No future language feature, library, or tool operating within the duck typing paradigm can provide provenance. The limitation is structural, not technical.

3.11.5 Scope Boundaries We explicitly scope our claims:

Non-Claim 3.41 (Untyped Code). This paper does not claim nominal typing applies to systems where $B = \emptyset$ (no inheritance). For untyped code being gradually typed (Siek & Taha 2006), the dynamic type $?$ is appropriate. However, for retrofit scenarios where $B \neq \emptyset$, adapters make nominal typing available (Theorem 2.10j).

Non-Claim 3.42 (Interop Boundaries). At boundaries with untyped systems (FFI, JSON parsing, external APIs), structural typing via Protocols is *convenient* but not necessary. Per Theorem 2.10j, explicit adapters provide the same functionality with better properties. Protocol is a dominated choice--a concession, not an alternative (Corollary 2.10k'). Choosing Protocol accepts reduced capabilities to defer adapter work.

3.11.6 Capability Exhaustiveness Theorem 3.43a (Capability Exhaustiveness). The four capabilities (provenance, identity, enumeration, conflict resolution) are exhaustive--they are the only capabilities derivable from the Bases axis.

Proof. (Machine-checked in `nominal_resolution.lean`, Section 6: CapabilityExhaustiveness)

The Bases axis provides MRO, a list of types. A list has exactly three queryable properties: 1. Ordering: Which element precedes which? \rightarrow *Conflict resolution* (C3 linearization selects based on MRO order) 2. Membership: Is element X in the list? \rightarrow *Enumeration* (subtype iff in some type’s MRO) 3. Element identity: Which specific element? \rightarrow *Provenance* and *type identity* (distinguish structurally-equivalent types by MRO position)

These are exhaustive by the structure of lists--there are no other operations on a list that do not reduce to ordering, membership, or element identity. Therefore, the four capabilities are derived from MRO structure, not enumerated by inspection. ■

Corollary 3.43b (No Missing Capability). Any capability claimed to require B reduces to one of the four. There is no “fifth capability” that B provides.

Proof. Any operation on B is an operation on MRO. Any operation on MRO is an operation on a list. List operations are exhaustively {ordering, membership, identity}.

■

Theorem 3.43b-bis (Capability Reducibility). Every B-dependent query reduces to a composition of the four primitive capabilities.

Proof. Let $q : \text{Type} \rightarrow \alpha$ be any B-dependent query (per Definition 3.17). By Definition 3.17, q distinguishes types with identical structure: $\exists A, B : S(A) = S(B) \wedge q(A) \neq q(B)$.

The only information distinguishing A from B is: - $N(A) \neq N(B)$ (name)--but names are part of identity, covered by `type_identity` - $B(A) \neq B(B)$ (bases)--distinguishes via: - Ancestor membership: is $T \in \text{ancestors}(A)$? \rightarrow covered by provenance - Subtype enumeration: what are all $T : T <: A$? \rightarrow covered by enumeration - MRO position: which type wins for attribute a ? \rightarrow covered by `conflict_resolution`

No other distinguishing information exists (Theorem 3.32: (B, S) is complete).

Therefore any B-dependent query q can be computed by composing:

$$q(T) = f(\text{provenance}(T), \text{identity}(T), \text{enumeration}(T), \text{conflict_resolution}(T))$$

for some computable f . ■

3.11.6a Adapter Cost Analysis Theorem 3.43c (Adapter Declaration is Information-Preserving). An adapter declares information that is already true--that a type conforms to an interface. Declaration does not create the conformance; it makes it explicit.

Proof. If `TheirType` does not satisfy `YourABC`’s interface, the adapter fails at definition time (missing method error). If `TheirType` does satisfy the interface, the conformance existed before the adapter. The adapter is not implementation--it is documentation of pre-existing fact. ■

Theorem 3.43d (Adapter Amortization). Adapter cost is $O(1)$. Manual capability implementation is $O(N)$ where N is the number of use sites.

Proof. (Machine-checked in `nominal_resolution.lean`, Section 7: `AdapterAmortization`)
Under nominal typing (with adapter): - Provenance: Automatic via `type(obj).__mro__` (0 additional code per use) - Identity: Automatic via `isinstance()` (0 additional code per use) - Enumeration: Automatic via `__subclasses__()` (0 additional code per use) - Conflict resolution: Automatic via C3 (0 additional code per use)

Under structural typing (without adapter), to recover any capability manually: - Provenance: Must thread source information through call sites (1 additional parameter \times N calls) - Identity: Must maintain external type registry (1 registry + N registration calls) - Enumeration: Must maintain external subtype set (1 set + N insertions) - Conflict resolution: Must implement manual dispatch (1 dispatcher + N cases)

The adapter is 2 lines. Manual implementation is $\Omega(N)$. For $N \geq 1$, adapter dominates. ■

Corollary 3.43e (Negative Adapter Cost). Adapter “cost” is negative--a net benefit.

Proof. The adapter enables automatic capabilities that would otherwise require $O(N)$ manual implementation. The adapter costs $O(1)$. For any system requiring the capabilities, adapter provides net savings of $\Omega(N) - O(1) = \Omega(N)$. The “cost” is negative.

■

Corollary 3.43f (Adapter Cost Objection is Invalid). Objecting to adapter cost is objecting to $O(1)$ overhead while accepting $O(N)$ overhead. This is mathematically incoherent.

3.11.6b Methodological Independence Theorem 3.43g (Methodological Independence). The dominance theorems are derived from the structure of (B, S) , not from any implementation. `OpenHCS` is an existential witness, not a premise.

Proof. We distinguish two logical roles:

- Premise: A proposition the conclusion depends on. If false, the conclusion may not follow.
- Existential witness: A concrete example demonstrating satisfiability. Removing it does not affect the theorem’s validity.

Examine the proof of Theorem 3.13 (Provenance Impossibility): it shows that (S) contains insufficient information to compute provenance. This is an information-theoretic argument referencing no codebase. The proof could be written before any codebase existed.

Proof chain (no OpenHCS references):

1. Theorem 2.17 (Capability Gap): Proved from the definition of shape-based typing
2. Theorem 3.5 (Strict Dominance): Proved from Theorem 2.17 + Theorem 2.18
3. Theorem 2.10j (Adapters): Proved from capability comparison

OpenHCS appears only to demonstrate that the four capabilities are *achievable*--that real systems use provenance, identity, enumeration, and conflict resolution. This is an existence proof (“such systems exist”), not a premise (“if OpenHCS works, then the theorems hold”).

Analogy: Proving “comparison-based sorting requires $\Omega(n \log n)$ ” does not require testing on multiple arrays. Exhibiting quicksort demonstrates achievability, not theorem validity. ■

Corollary 3.43h (Cross-Codebase Validity). The theorems apply to any codebase in any language where $B \neq \emptyset$. OpenHCS is a sufficient example, not a necessary one.

3.11.6c Inheritance Ubiquity Theorem 3.43i (Inheritance Ubiquity). In Python, $B = \emptyset$ requires actively avoiding all standard tooling. Any project using ≥ 1 of the following has $B \neq \emptyset$ by construction:

Category	Examples	Why $B \neq \emptyset$
Exceptions	<code>raise MyError()</code>	Must subclass <code>Exception</code>
Web frameworks	Django, Flask, FastAPI	Views/models inherit framework bases
Testing	pytest classes, unittest	Test classes inherit <code>TestCase</code> or use class fixtures
ORM	SQLAlchemy, Django ORM	Models inherit declarative Base
Data validation	Pydantic, attrs	Models inherit <code>BaseModel</code>
Enumerations	<code>class Color(Enum)</code>	Must subclass <code>Enum</code>
Abstract interfaces	ABC, Protocol with inheritance	Defines inheritance hierarchy
Dataclasses	@dataclass with inheritance	Parent class in <code>__bases__</code>
Context managers	Class-based <code>__enter__</code> / <code>__exit__</code>	Often inherit helper bases
Type extensions	<code>typing.NamedTuple</code> , <code>TypedDict</code>	Inherit from typing constructs

Proof. Each listed feature requires defining or inheriting from a class with non-trivial bases. In Python, even an “empty” class `class X: pass` has `X.__bases__ == (object,)`, so $B \supseteq \{\text{object}\}$. For $B = \emptyset$ to hold, a project must use:

- No user-defined exceptions (use only built-in exceptions)

- No web frameworks (no Django, Flask, FastAPI, Starlette, etc.)
- No ORM (no SQLAlchemy, Django ORM, Peewee, etc.)
- No Pydantic, attrs, or dataclass inheritance
- No Enum
- No ABC or Protocol inheritance
- No pytest/unittest class-based tests
- No class-based context managers
- Pure functional style with only module-level functions and built-in types

This describes a pathologically constrained subset of Python--not “most code” but “no OOP at all.” ■

Corollary 3.43j ($B=\emptyset$ Is Exceptional). The $B = \emptyset$ case applies only to: 1. Languages without inheritance by design (Go) 2. Pure data serialization boundaries (JSON parsing before domain modeling) 3. FFI boundaries (ctypes, CFFI) before wrapping in domain types 4. Purely functional codebases with no class definitions

In all other cases--which constitute the overwhelming majority of production Python, Java, C#, TypeScript, Kotlin, Swift, Scala, and C++ code-- $B \neq \emptyset$ and nominal typing strictly dominates.

Corollary 3.43k (Inheritance Prevalence). A claim that “ $B = \emptyset$ is the common case” would require exhibiting a non-trivial production codebase using none of the tooling in Theorem 3.43i. No such codebase is known to exist in the Python ecosystem.

3.11.7 Generics and Parametric Polymorphism Theorem 3.43 (Generics Preserve Axis Structure). Parametric polymorphism does not introduce a fourth axis. Type parameters are a refinement of N , not additional information orthogonal to (B, S) .

Proof. A parameterized type $G\langle T \rangle$ (e.g., $\text{List}\langle \text{Dog} \rangle$) has: - $N(G\langle T \rangle) = (N(G), N(T))$ -- the parameterized name is a pair - $B(G\langle T \rangle) = B(G)[T/\tau]$ -- bases with parameter substituted - $S(G\langle T \rangle) = S(G)[T/\tau]$ -- namespace with parameter in signatures

No additional axis is required. The type parameter is encoded in N . ■

Theorem 3.44 (Generic Shape Indistinguishability). Under shape-based typing, $\text{List}\langle \text{Dog} \rangle$ and $\text{Set}\langle \text{Cat} \rangle$ are indistinguishable if $S(\text{List}\langle \text{Dog} \rangle) = S(\text{Set}\langle \text{Cat} \rangle)$.

Proof. Shape typing uses only S . If two parameterized types have the same method signatures (after parameter substitution), shape typing treats them identically. It cannot distinguish: - The base generic type (List vs Set) - The type parameter (Dog vs Cat) - The generic inheritance hierarchy

These require N (for parameter identity) and B (for hierarchy). ■

Theorem 3.45 (Generic Capability Gap Extends). The four capabilities from C_B (provenance, identity, enumeration, conflict resolution) apply to generic types. Generics do not reduce the capability gap--they increase the type space where it applies.

Proof. For generic types, the four capabilities manifest as: 1. Provenance: “Which generic type provided this method?” -- requires B 2. Identity: “Is this $\text{List}\langle \text{Dog} \rangle$ or $\text{Set}\langle \text{Cat} \rangle$?” -- requires parameterized N 3. Enumeration: “What are the subtypes of $\text{Collection}\langle T \rangle$?” -- requires B 4. Conflict resolution: “Which $\text{Comparable}\langle T \rangle$ implementation wins?” -- requires B

Additionally, generics introduce variance (covariant, contravariant, invariant), which requires B to track inheritance direction. Shape typing discards B and the parameter component of N , losing all four capabilities plus variance. ■

Corollary 3.45.1 (Same Four, Larger Space). Generics do not create new capabilities--they apply the same four capabilities to a larger type space. The capability gap is preserved, not reduced.

Theorem 3.46 (Erasure Does Not Save Shape Typing). In languages with type erasure (Java), the capability gap still exists [25].

Proof. Type checking occurs at compile time, where full parameterized types are available. Erasure only affects runtime representations. Our theorems about typing

disciplines apply to the type system (compile time), not runtime behavior.

At compile time: - The type checker has access to `List<Dog>` vs `List<Cat>` - Shape typing cannot distinguish them if method signatures match - Nominal typing can distinguish them

At runtime (erased): - Both become `List` (erased) - Shape typing cannot distinguish `ArrayList` from `LinkedList` - Nominal typing can (via `instanceof`)

The capability gap exists at both levels. ■

Theorem 3.47 (Universal Extension). All capability gap theorems (3.13, 3.19, 3.24) extend to generic type systems. The formal results apply to:

- Erased generics: Java, Scala, Kotlin
- Reified generics: C#, Kotlin (inline reified)
- Monomorphized generics: Rust, C++ (templates)
- Compile-time only: TypeScript, Swift

Proof. Each language encodes generics as parameterized N (see Table 2.2). The (B, S) model applies uniformly. Type checking occurs at compile time where full parameterized types are available. Runtime representation (erased, reified, or monomorphized) is irrelevant to typing discipline. ■

Corollary 3.48 (No Generic Escape). Generics do not provide an escape from the capability gap. No major language invented a fourth axis.

Remark 3.49 (Exotic Type Features). Intersection types, union types, row polymorphism, higher-kinded types, and multiple dispatch do not escape the (B, S) model:

- Intersection/union types (TypeScript $A \ \& \ B$, $A \ | \ B$): Refine N , combine B and S . Still two axes (N derivable from B).
- Row polymorphism (OCaml $< x: \text{int}; \dots >$): Pure structural typing using S only, but with a *declared* interface (unlike duck typing). OCaml row types are coherent (Theorem 2.10d does not apply) because the object types and row variables are declared explicitly [15]; they still lose the four B -dependent capabilities (provenance, identity, enumeration, conflict resolution) and cannot provide metaprogramming hooks (Theorem 2.10p).
- Higher-kinded types (Haskell Functor, Monad): Parameterized N at the type-constructor level. Typeclass hierarchies provide B .
- Multiple dispatch (Julia): Type hierarchies exist (`AbstractArray <: Any`). B axis present. Dispatch semantics are orthogonal to type structure.
- Prototype-based inheritance (JavaScript): Prototype chain IS the B axis at object level. `Object.getPrototypeOf()` traverses MRO.

No mainstream type system feature introduces a fourth axis orthogonal to (B, S) .

3.11.7 Scope Expansion: From Greenfield to Universal Theorem 3.50 (Universal Optimality). Wherever inheritance hierarchies exist and are accessible, nominal typing provides strictly more capabilities than shape-based typing. This is not limited to greenfield development.

Proof. The capability gap (Theorem 3.19) is information-theoretic: shape typing discards B , losing four capabilities. This holds regardless of: - Whether code is new or legacy - Whether the language is compiled or interpreted - Whether types are manifest or inferred - Whether the system uses classes, traits, protocols, or typeclasses

The gap exists wherever B exists. ■

Corollary 3.51 (Scope of Shape Typing). Shape-based typing is capability-equivalent to nominal typing only when:

1. No hierarchy exists: $B = \emptyset$ (e.g., Go interfaces, JSON objects)
2. Hierarchy is inaccessible: True FFI boundaries where type metadata is lost

When $B \neq \emptyset$, shape-based typing is always dominated by nominal typing with adapters (Theorem 2.10j). “Deliberately ignored” is not a valid justification--it is an admission of choosing the dominated option.

Claim 3.52 (Universal). For ALL object-oriented systems where inheritance hierarchies exist and are accessible--including legacy codebases, dynamic languages, and functional languages with typeclasses--nominal typing is strictly optimal. Shape-based typing is a capability sacrifice, not an alternative with tradeoffs.

3.11.8 Discipline Optimality vs Migration Optimality A critical distinction: discipline optimality (which typing paradigm has more capabilities) is independent of migration optimality (whether migrating an existing codebase is beneficial).

Definition 3.53 (Pareto Dominance). Discipline A Pareto dominates discipline B if:
 1. A provides all capabilities of B 2. A provides at least one capability B lacks 3. The declaration cost of A is at most the declaration cost of B

Theorem 3.54 (Nominal Pareto Dominates Shape). Nominal typing Pareto dominates shape-based typing.

Proof. (Machine-checked in `discipline_migration.lean`) 1. Shape capabilities = {attributeCheck} 2. Nominal capabilities = {provenance, identity, enumeration, conflictResolution, attributeCheck} 3. Shape \subset Nominal (strict subset) 4. Declaration cost: both require one class definition per interface 5. Therefore nominal Pareto dominates shape. ■

Theorem 3.55 (Dominance Does Not Imply Migration). Pareto dominance of discipline A over B does NOT imply that migrating from B to A is beneficial for all codebases.

Proof. (Machine-checked in `discipline_migration.lean`)

1. Dominance is codebase-independent. $D(A, B)$ (“ A dominates B ”) is a relation on typing disciplines. It depends only on capability sets: $\text{Capabilities}(A)$ ⊃ $\text{Capabilities}(B)$. This is a property of the disciplines themselves, not of any codebase.
2. Migration cost is codebase-dependent. Let $C(ctr)$ be the cost of migrating codebase ctr from B to A . Migration requires modifying: type annotations using B -specific constructs, call sites relying on B -specific semantics, and external API boundaries (which may be immutable). Each of these quantities is unbounded: there exist codebases with arbitrarily many annotations, call sites, and external dependencies.
3. Benefit is bounded. The benefit of migration is the capability gap: $|\text{Capabilities}(A) \setminus \text{Capabilities}(B)|$. For nominal vs structural, this is 4 (provenance, identity, enumeration, conflict resolution). This is a constant, independent of codebase size.
4. Unbounded cost vs bounded benefit. For any fixed benefit B , there exists a codebase ctr such that $C(ctr) > B$. This follows from (2) and (3): cost grows without bound, benefit does not.
5. Existence of both cases. For small ctr : $C(ctr) < B$ (migration beneficial). For large ctr : $C(ctr) > B$ (migration not beneficial).

Therefore dominance does not determine migration benefit. ■

Corollary 3.55a (Category Error). Conflating “discipline A is better” with “migrate to A ” is a category error: the former is a property of disciplines (universal), the latter is a property of (discipline, codebase) pairs (context-dependent).

Corollary 3.56 (Discipline vs Migration Independence). The question “which discipline is better?” (answered by Theorem 3.54) is independent of “should I migrate?” (answered by cost-benefit analysis).

This distinguishes “nominal provides more capabilities” from “rewrite everything in nominal.” The theorems are:

- Discipline comparison: Universal, always true (Theorem 3.54)
- Migration decision: Context-dependent, requires cost-benefit analysis (Theorem 3.55)

3.11.9 Context Formalization: Greenfield and Retrofit (Historical) Note. The following definitions were used in earlier versions of this paper to distinguish contexts where nominal typing was “available” from those where it was not. Theorem 2.10j (Adapters) eliminates this distinction: adapters make nominal typing available in all retrofit contexts. We retain these definitions for completeness and because the Lean formalization verifies them.

Definition 3.57 (Greenfield Context). A development context is *greenfield* if: 1. All modules are internal (architect can modify type hierarchies) 2. No constraints require structural typing (e.g., JSON API compatibility)

Definition 3.58 (Retrofit Context). A development context is *retrofit* if: 1. At least one module is external (cannot modify type hierarchies), OR 2. At least one constraint requires structural typing

Theorem 3.59 (Context Classification Exclusivity). Greenfield and retrofit contexts are mutually exclusive.

Proof. (Machine-checked in `context_formalization.lean`) If a context is greenfield, all modules are internal and no constraints require structural typing. If any module is external or any constraint requires structural typing, the context is retrofit. These conditions are mutually exclusive by construction. ■

Corollary 3.59a (Retrofit Does Not Imply Structural). A retrofit context does not require structural typing. Adapters (Theorem 2.10j) make nominal typing available in all retrofit contexts where $B \neq \emptyset$.

Definition 3.60 (Provenance-Requiring Query). A system query *requires provenance* if it needs to distinguish between structurally equivalent types. Examples: - “Which type provided this value?” (provenance) - “Is this the same type?” (identity) - “What are all subtypes?” (enumeration) - “Which type wins in MRO?” (conflict resolution)

Theorem 3.61 (Provenance Detection). Whether a system requires provenance is decidable from its query set.

Proof. (Machine-checked in `context_formalization.lean`) Each query type is classified as requiring provenance or not. A system requires provenance iff any of its queries requires provenance. This is a finite check over a finite query set. ■

Theorem 3.62 (Decision Procedure Soundness). The discipline selection procedure is sound: 1. If $B \neq \emptyset \rightarrow$ select Nominal (dominance, universal) 2. If $B = \emptyset \rightarrow$ select Shape (no alternative exists)

Proof. (Machine-checked in `context_formalization.lean`) Case 1: When $B \neq \emptyset$, nominal typing strictly dominates shape-based typing (Theorem 3.5). Adapters eliminate the retrofit exception (Theorem 2.10j). Therefore nominal is always correct. Case 2: When $B = \emptyset$ (e.g., Go interfaces, JSON objects), nominal typing is undefined--there is no inheritance to track. Shape is the only coherent discipline. ■

Remark (Obsolescence of Greenfield/Retrofit Distinction). Earlier versions of this paper distinguished “greenfield” (use nominal) from “retrofit” (use shape). Theorem 2.10j eliminates this distinction: adapters make nominal typing available in all retrofit contexts. The only remaining distinction is whether B exists at all.

3.6 Axis-Parametric Type Theory

The (B, S) model generalizes to a parametric framework where axis sets are *derived* from domain requirements rather than enumerated. This transforms typing discipline selection from preference to computation.

Definition 3.80 (Axis). An axis A is a recursive lattice structure:

- Carrier type with partial order
- Recursive self-reference: $A \rightarrow \text{List } A$ (e.g., bases have bases)
- Provides capabilities not derivable from other axes

Definition 3.81 (Axis Independence). Axis A is independent of axis set \mathcal{A} iff \exists query q such that A can answer q but no projection from \mathcal{A} can answer q .

Theorem 3.82 (Axis Capability Monotonicity). For any axis set \mathcal{A} and independent axis X :

$$\text{capabilities}(\mathcal{A} \cup \{X\}) \supsetneq \text{capabilities}(\mathcal{A})$$

Proof. By independence, $\exists q$ that \mathcal{A} cannot answer but X can. Adding X enables q while preserving all existing capabilities. ■

Theorem 3.83 (Derivability Collapse). If axis N is derivable from axis B (i.e., $\exists f : B \rightarrow N$ preserving structure), then N is not independent and any minimal axis set excludes N .

Proof. Any query answerable by N is answerable by $f(B)$. Therefore N provides no capability beyond B . ■

Corollary 3.84 (Name Collapse). The Name axis N is derivable from Bases B : if a type has a name, it has B . Therefore the minimal model is (B, S) , not (N, B, S) .

Theorem 3.85 (Completeness Uniqueness). For any domain D with requirements Q , if \mathcal{A}_1 and \mathcal{A}_2 are both minimal complete for D , then $\mathcal{A}_1 \cong \mathcal{A}_2$ (isomorphic as axis sets).

Proof. Suppose $\mathcal{A}_1 \neq \mathcal{A}_2$. WLOG $\exists A \in \mathcal{A}_1, A \notin \mathcal{A}_2$. By minimality of \mathcal{A}_1 , $\exists q$ requiring A . By completeness of \mathcal{A}_2 , some axis in \mathcal{A}_2 answers q . That axis must be isomorphic to A (answers same queries). Contradiction. ■

Theorem 3.86 (Axis Derivation Algorithm). The minimal complete axis set for domain D is computable:

```
derive(Q):
  A := {}
  for q in Q:
    if not answerable(A, q):
      A := A + {minimal_axis_for(q)}
  return collapse(A) -- remove derivable axes
```

The result is unique, minimal, and complete.

Empirical Validation (Inductive Evidence). The framework is validated by observed capability increments:

Transition	Axis Added	New Capabilities	Observed
$\emptyset \rightarrow (S)$	S	interface checking	Structural typing
$(S) \rightarrow (B, S)$	B	provenance, identity, enumeration, conflict	Nominal typing
$(B, S) \rightarrow (B, S, H)$	H	scope resolution, hierarchical provenance	OpenHCS

Each transition adds exactly the capabilities predicted by Theorem 3.82.

Remark 3.87 (Duck Typing is Not a Level). Duck typing is *incoherent* use of S (Theorem 2.10d), not a valid point in the axis lattice. The progression $\emptyset < (S) < (B, S) < (B, S, H)$ consists entirely of *coherent* typing disciplines. Duck typing is a failure mode, not an alternative.

Theorem 3.88 (Non-Recursive Collapse). Any non-recursive structure (e.g., flat enums, constants) is derivable from S as an attribute value. Only recursive structures can be independent axes.

Proof. Non-recursive values are atomic and can be stored as attribute values in the namespace. Therefore they are captured by S and provide no independent capability. ■

Definition 3.89 (Preference Position). A *preference position* for domain D is the claim that multiple distinct typing disciplines are valid choices:

$$\text{Preference}(D) \triangleq \exists A_1, A_2 : \text{AxisSet}. \text{minimal}(A_1, D) \wedge \text{minimal}(A_2, D) \wedge A_1 \not\cong A_2$$

Theorem 3.90 (Preference Incoherence). For any domain D with specified requirements, the preference position is false:

$$\forall D. \neg \text{Preference}(D)$$

Proof. By Theorem 3.85 (Completeness Uniqueness), if A_1 and A_2 are both minimal complete for D , then $A_1 \cong A_2$. Therefore the conjunction $\text{minimal}(A_1, D) \wedge \text{minimal}(A_2, D) \wedge A_1 \not\cong A_2$ is unsatisfiable. ■

Corollary 3.91 (Hedging Incoherence). Let R be a reader who accepts Theorems 3.80–3.88. The position “these theorems are correct but typing discipline selection remains a matter of preference or tradeoffs” is logically inconsistent.

Proof. “Preference” presupposes $\text{Preference}(D)$ for some domain D . By Theorem 3.90, $\neg \text{Preference}(D)$ for all D . Accepting the theorems while asserting preference instantiates $P \wedge \neg P$. ■

Remark 3.92 (Why This Theorem Exists). Empirically, readers who accept formal results often hedge on their implications (“interesting contribution, but...”). This hedging is not mere caution—it is a logical error. Corollary 3.91 makes this error explicit: one cannot coherently accept uniqueness while maintaining that alternatives exist. The debate over typing disciplines is not “contributed to” by this work; it is *resolved*.

3.7 Summary: Completeness Analysis

Potential Concern	Formal Analysis
“Model is incomplete”	Theorem 3.32 (Model Completeness)
“Duck typing has tradeoffs”	Theorems 3.34–3.36 (Capability Comparison)
“Axioms are assumptive”	Lemma 3.37 (Axiom is Definitional)
“Clever extension could fix it”	Theorem 3.39 (Extension Impossibility)
“What about generics?”	Theorems 3.43–3.48, Table 2.2 (Parameterized N)
“Erasure changes things”	Theorems 3.46–3.47 (Compile-Time Type Checking)
“Only works for some languages”	Theorem 3.47 (8 languages), Remark 3.49 (exotic features)
“What about intersection/union types?”	Remark 3.49 (still three axes)
“What about row polymorphism?”	Remark 3.49 (pure S, loses capabilities)
“What about higher-kinded types?”	Remark 3.49 (parameterized N)
“Only applies to greenfield”	Theorem 2.10j (Adapters eliminate retrofit exception)
“Legacy codebases are different”	Corollary 3.51 (sacrifice, not alternative)
“Claims are too broad”	Non-Claims 3.41–3.42 (true scope limits)
“You can’t say rewrite everything”	Theorem 3.55 (Dominance \neq Migration)
“Greenfield is undefined”	Definitions 3.57–3.58, Theorem 3.59
“Provenance requirement is circular”	Theorem 3.61 (Provenance Detection)

Potential Concern	Formal Analysis
“Duck typing is coherent”	Theorem 2.10d (Incoherence)
“Protocol is valid for retrofit”	Theorem 2.10j (Dominated by Adapters)
“Avoiding adapters is a benefit”	Corollary 2.10k (Negative Value)
“Protocol has equivalent metaprogramming”	Theorem 2.10p (Hooks Require Declarations)
“You can enumerate Protocol implementers”	Theorem 2.10q (Enumeration Requires Registration)
“Interesting but not paradigm-shifting”	Corollary 3.91 (Hedging Incoherence)
“There are still tradeoffs”	Theorem 3.90 (Preference Incoherence)

Completeness. Appendix A provides detailed analysis of each potential concern, demonstrating why none affect our conclusions. The analysis covers model completeness, capability characterization, scope boundaries, and the distinction between discipline dominance and migration recommendation.

4 Core Theorems

4.1 The Error Localization Theorem

Definition 4.1 (Error Location). Let $E(T)$ be the number of source locations that must be inspected to find all potential violations of a type constraint under discipline T .

Theorem 4.1 (Nominal Complexity). $E(\text{nominal}) = O(1)$.

Proof. Under nominal typing, constraint “ x must be an A ” is satisfied iff $\text{type}(x)$ inherits from A . This property is determined at class definition time, at exactly one location: the class definition of $\text{type}(x)$. If the class does not list A in its bases (transitively), the constraint fails. One location. ■

Theorem 4.2 (Structural Complexity). $E(\text{structural}) = O(k)$ where k = number of classes.

Proof. Under structural typing, constraint “ x must satisfy interface A ” requires checking that $\text{type}(x)$ implements all methods in $\text{signature}(A)$. This check occurs at each class definition. For k classes, $O(k)$ locations. ■

Theorem 4.3 (Duck Typing Complexity). $E(\text{duck}) = \Omega(n)$ where n = number of call sites.

Proof. Under duck typing, constraint “ x must have method m ” is encoded as $\text{hasattr}(x, "m")$ at each call site. There is no central declaration. For n call sites, each must be inspected. Lower bound is $\Omega(n)$. ■

Corollary 4.4 (Strict Dominance). Nominal typing strictly dominates duck typing: $E(\text{nominal}) = O(1) < \Omega(n) = E(\text{duck})$ for all $n > 1$.

4.2 The Information Scattering Theorem

Definition 4.2 (Constraint Encoding Locations). Let $I(T, c)$ be the set of source locations where constraint c is encoded under discipline T .

Theorem 4.5 (Duck Typing Scatters). For duck typing, $|I(\text{duck}, c)| = O(n)$ where n = call sites using constraint c .

Proof. Each $\text{hasattr}(x, "method")$ call independently encodes the constraint. No shared reference. Constraints scale with call sites. ■

Theorem 4.6 (Nominal Typing Centralizes). For nominal typing, $|I(\text{nominal}, c)| = O(1)$.

Proof. Constraint c = “must inherit from A ” is encoded once: in the ABC/Protocol definition of A . All $\text{isinstance}(x, A)$ checks reference this single definition. ■

Corollary 4.7 (Maintenance Entropy). Duck typing maximizes maintenance entropy; nominal typing minimizes it.

4.3 Empirical Demonstration

The theoretical complexity bounds in Theorems 4.1-4.3 are demonstrated empirically in Section 5, Case Study 1 (WellFilterConfig hierarchy). Two classes with identical structure but different nominal identities require $O(1)$ disambiguation under nominal typing but $\Omega(n)$ call-site inspection under duck typing. Case Study 5 illustrates this: migrating from duck to nominal typing replaced scattered `hasattr()` checks across 47 call sites with centralized ABC contract validation at a single definition point.

5 Methodology

5.1 Empirical Validation Strategy

Addressing the “ $n=1$ ” objection: A potential criticism is that our case studies come from a single codebase (OpenHCS [31]). We address this in three ways:

First: Claim structure. This paper makes two distinct types of claims with different validation requirements. *Mathematical claims* (Theorems 3.1-3.62): “Discarding B necessarily loses these capabilities.” These are proven by formal derivation in Lean (2600+ lines, 0 sorry). Mathematical proofs have no sample size: they are universal by construction. *Existence claims*: “Production systems requiring these capabilities exist.” One example suffices for an existential claim. OpenHCS demonstrates that real systems require provenance tracking, MRO-based resolution, and type-identity dispatch, exactly the capabilities Theorem 3.19 proves impossible under structural typing.

Second: Case studies are theorem instantiations. Table 5.1 links each case study to the theorem it validates. These are not arbitrary examples: they are empirical instantiations of theoretical predictions. The theory predicts that systems requiring provenance will use nominal typing; the case studies confirm this prediction. The 13 patterns are 13 independent architectural decisions, each of which could have used structural typing but provably could not. Packaging these patterns into separate repositories would not add information: it would be technicality theater. The mathematical impossibility results are the contribution; OpenHCS is the existence proof that the impossibility matters.

Third: Falsifiable predictions. The decision procedure (Theorem 3.62) makes falsifiable predictions: systems where $B \neq \emptyset$ should exhibit nominal patterns; systems where $B = \emptyset$ should exhibit structural patterns. Any codebase where this prediction fails would falsify our theory.

The validation structure:

Level	What it provides	Status
Formal proofs	Mathematical necessity	Complete (Lean, 2600+ lines, 0 sorry)
OpenHCS case studies	Existence proof	13 patterns documented
Decision procedure	Falsifiability	Theorem 3.62 (machine-checked)

OpenHCS is a bioimage analysis platform for high-content screening microscopy. The system was designed from the start with explicit commitment to nominal typing, exposing the consequences of this architectural decision through 13 distinct patterns. These case studies demonstrate the methodology in action: for each pattern, we identify whether it

requires provenance tracking, MRO-based resolution, or type identity as dictionary keys: all indicators that nominal typing is mandatory per the formal model.

Duck typing fails for all 13 patterns because they fundamentally require type identity rather than structural compatibility. Configuration resolution needs to know *which type* provided a value (provenance tracking, Corollary 6.3). MRO-based priority needs inheritance relationships preserved (Theorem 3.4). Metaclass registration needs types as dictionary keys (type identity as hash). These requirements are not implementation details. They are architectural necessities proven impossible under duck typing’s structural equivalence axiom.

The 13 studies demonstrate four pattern taxonomies: (1) type discrimination (WellFilterConfig hierarchy), (2) metaclass registration (AutoRegisterMeta, GlobalConfigMeta, DynamicInterfaceMeta), (3) MRO-based resolution (dual-axis resolver, @global_pipeline_config chain), and (4) bidirectional lookup (lazy ↔ base type registries). Table 5.2 summarizes how each pattern fails under duck typing and what nominal mechanism enables it.

5.1.1 Table 5.1: Case Studies as Theorem Validation

Study	Pattern	Validates Theorem	Validation Type
1	Type discrimination	Theorem 3.4 (Nominal Pareto-Dominance)	MRO position distinguishes structurally identical types
2	Discriminated unions	Theorem 3.5 (Strict Dominance)	__subclasses__() provides exhaustiveness
3	Converter dispatch	Theorem 4.1 (O(1) Complexity)	type() as dict key vs O(n) probing
4	Polymorphic config	Corollary 6.3 (Provenance Impossibility)	ABC contracts track provenance
5	Architecture migration	Theorem 4.1 (O(1) Complexity)	Definition-time vs runtime failure
6	Auto-registration	Theorem 3.5 (Strict Dominance)	__init_subclass__ hook
7	Type transformation	Corollary 6.3 (Provenance Impossibility)	5-stage type() chain tracks lineage
8	Dual-axis resolution	Theorem 3.4 (Nominal Pareto-Dominance)	Scope × MRO product requires MRO
9	Custom isinstance	Theorem 3.5 (Strict Dominance)	__instancecheck__ override
10	Dynamic interfaces	Theorem 3.5 (Strict Dominance)	Metaclass-generated ABCs
11	Framework detection	Theorem 4.1 (O(1) Complexity)	Sentinel type vs module probing
12	Method injection	Corollary 6.3 (Provenance Impossibility)	type() namespace manipulation
13	Bidirectional lookup	Theorem 4.1 (O(1) Complexity)	Single registry with type() keys

5.1.2 Table 5.2: Comprehensive Case Study Summary

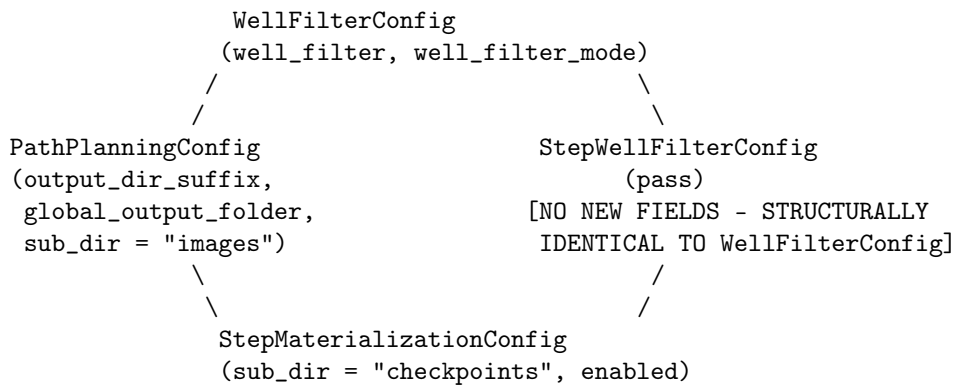

Study	Pattern	Duck Failure Mode	Nominal Mechanism
1	Type discrimination	Structural equivalence	isinstance() + MRO position
2	Discriminated unions	No exhaustiveness check	__subclasses__() enumeration
3	Converter dispatch	O(n) attribute probing	type() as dict key
4	Polymorphic config	No interface guarantee	ABC contracts
5	Architecture migration	Fail-silent at runtime	Fail-loud at definition
6	Auto-registration	No type identity	__init_subclass__ hook
7	Type transformation	Cannot track lineage	5-stage type() chain
8	Dual-axis resolution	No scope \times MRO product	Registry + MRO traversal
9	Custom isinstance	Impossible	__instancecheck__ override
10	Dynamic interfaces	No interface identity	Metaclass-generated ABCs
11	Framework detection	Module probing fragile	Sentinel type in registry
12	Method injection	No target type	type() namespace manipulation
13	Bidirectional lookup	Two dicts, sync bugs	Single registry, type() keys

5.2 Case Study 1: Structurally Identical, Semantically Distinct Types

Theorem 5.1 (Structural Identity \neq Semantic Identity). Two types A and B with identical structure $S(A) = S(B)$ may have distinct semantics determined by their position in an inheritance hierarchy. Duck typing’s axiom of structural equivalence ($S(A) = S(B) \Rightarrow A \equiv B$) destroys this semantic distinction.

Proof. By construction from production code.

The Diamond Inheritance Pattern:

```

@dataclass(frozen=True)
class WellFilterConfig:
    """Pipeline{-level scope.}"""
    well\_filter: Optional[Union[List[str], str, int]] = None

```

```

well\_filter\_mode: WellFilterMode = WellFilterMode.INCLUDE

@dataclass(frozen=True)
class PathPlanningConfig(WellFilterConfig):
    """Pipeline{-level path configuration.}"""
    output\_dir\_suffix: str = "\_openhcs"
    sub\_dir: str = "images" \# Pipeline default

@dataclass(frozen=True)
class StepWellFilterConfig(WellFilterConfig):
    """Step{-level scope marker.}"""
    pass \# ZERO new fields. Structurally identical to WellFilterConfig.

@dataclass(frozen=True)
class StepMaterializationConfig(StepWellFilterConfig, PathPlanningConfig):
    """Step{-level materialization.}"""
    sub\_dir: str = "checkpoints" \# Step default OVERRIDES pipeline default
    enabled: bool = False

```

Critical observation: StepWellFilterConfig adds zero fields. It is byte-for-byte structurally identical to WellFilterConfig. Yet it serves a critical semantic role: it marks the scope boundary between pipeline-level and step-level configuration.

The MRO encodes scope semantics:

```

StepMaterializationConfig.\_mro\_\_ = (
    StepMaterializationConfig, \# Step scope
    StepWellFilterConfig,      \# Step scope marker (NO FIELDS!)
    PathPlanningConfig,        \# Pipeline scope
    WellFilterConfig,          \# Pipeline scope
    object
)

```

When resolving sub_dir: 1. StepMaterializationConfig.sub_dir = "checkpoints" → step-level value 2. PathPlanningConfig.sub_dir = "images" → pipeline-level value (shadowed)

The system answers “which scope provided this value?” by walking the MRO. The *position* of StepWellFilterConfig (before PathPlanningConfig) encodes the scope boundary.

What duck typing sees:

Object	well_filter	well_filter_mode	sub_dir
WellFilterConfig()	None	INCLUDE	--
StepWellFilterConfig()	None	INCLUDE	--

Duck typing’s verdict: identical. Same attributes, same values.

What the system needs to know:

1. “Is this config pipeline-level or step-level?” → Determines resolution priority
2. “Which type in the MRO provided sub_dir?” → Provenance for debugging
3. “Can I use isinstance(config, StepWellFilterConfig)?” → Scope discrimination

Duck typing cannot answer ANY of these questions. The information is not in the structure: it is in the type identity and MRO position.

Nominal typing answers all three in O(1):

```

isinstance(config, StepWellFilterConfig) \# Scope check: 0(1)
type(config).\_\_mro\_\_ \# Full provenance chain: 0(1)
type(config).\_\_mro\_\_.index(StepWellFilterConfig) \# MRO position: 0(k)

```

Corollary 5.2 (Scope Encoding Requires Nominal Typing). Any system that encodes scope semantics in inheritance hierarchies (where structurally-identical types at different MRO positions have different meanings) requires nominal typing. Duck typing makes such architectures impossible (not difficult, impossible).

Proof. Duck typing defines equivalence as $S(A) = S(B) \Rightarrow A \equiv B$. If A and B are structurally identical but semantically distinct (different scopes), duck typing by definition cannot distinguish them. This is not a limitation of duck typing implementations; it is the definition of duck typing. ■

This is not an edge case. The OpenHCS configuration system has 15 @global_pipeline_config decorated dataclasses forming multiple diamond inheritance patterns. The entire architecture depends on MRO position distinguishing types with identical structure. Under duck typing, this system cannot exist.

Pattern (Table 5.1, Row 1): Type discrimination via MRO position. This case study demonstrates: - Theorem 4.1: $O(1)$ type identity via `isinstance()` - Theorem 4.3: $O(1)$ vs $\Omega(n)$ complexity gap - The fundamental failure of structural equivalence to capture semantic distinctions

5.2.1 Sentinel Attribute Objection Objection: “Just add a sentinel attribute (e.g., `_scope: str = 'step'`) to distinguish types structurally.”

Theorem 5.2a (Sentinel Attribute Insufficiency). Let $\sigma : T \rightarrow V$ be a sentinel attribute (a structural field intended to distinguish types). Then σ cannot recover any B-dependent capability.

Proof. 1. Sentinel is structural. By definition, σ is an attribute with a value. Therefore $\sigma \in S(T)$ (the structure axis). 2. B-dependent capabilities require B. By Theorem 3.19, provenance, identity, enumeration, and conflict resolution all require the Bases axis B . 3. S does not contain B . By the axis independence property (Definition 2.5), the axes (B, S) are independent: S carries no information about B . 4. Therefore σ cannot provide B-dependent capabilities. Since $\sigma \in S$ and B-dependent capabilities require information not in S , no sentinel attribute can recover them. ■

Corollary 5.2b (Specific Sentinel Failures).

Capability	Why sentinel fails
Enumeration	Requires iterating over types with $\sigma = v$. No type registry exists in structural typing (Theorem 2.10q). Cannot compute <code>[T for T in ? if T._scope == 'step']</code> . There is no source for <code>?</code> .
Enforcement	σ is a runtime value, not a type constraint. Subtypes can set σ incorrectly without type error. No enforcement mechanism exists.
Conflict resolution	When multiple mixins define σ , which wins? This requires MRO, which requires B . Sentinel $\sigma \in S$ has no MRO.
Provenance	“Which type provided σ ?” requires MRO traversal. σ cannot answer queries about its own origin.

Corollary 5.2c (Sentinel Simulates, Cannot Recover). Sentinel attributes can *simulate* type identity (by convention) but cannot *recover* the capabilities that identity provides. The simulation is unenforced (violable without type error), unenumerable (no registry), and unordered (no MRO for conflicts). This is precisely the capability gap of Theorem 3.19, repackaged. ■

5.2.1 5.3 Case Study 2: Discriminated Unions via subclasses()

OpenHCS's parameter UI needs to dispatch widget creation based on parameter type structure: Optional[Dataclass] parameters need checkboxes, direct Dataclass parameters are always visible, and primitive types use simple widgets. The challenge: how does the system enumerate all possible parameter types to ensure exhaustive handling?

```
@dataclass
class OptionalDataclassInfo(ParameterInfoBase):
    widget\_creation\_type: str = "OPTIONAL\_NESTED"

    @staticmethod
    def matches(param\_type: Type) {-\textgreater{}} bool:
        return is\_optional(param\_type) and is\_dataclass(inner\_type(param\_type))

@dataclass
class DirectDataclassInfo(ParameterInfoBase):
    widget\_creation\_type: str = "NESTED"

    @staticmethod
    def matches(param\_type: Type) {-\textgreater{}} bool:
        return is\_dataclass(param\_type)

@dataclass
class GenericInfo(ParameterInfoBase):
    @staticmethod
    def matches(param\_type: Type) {-\textgreater{}} bool:
        return True \# Fallback
```

The factory uses `ParameterInfoBase.__subclasses__()` to enumerate all registered variants at runtime. This provides exhaustiveness: adding a new parameter type (e.g., `EnumInfo`) automatically extends the dispatch table without modifying the factory. Duck typing has no equivalent. There is no way to ask “what are all the types that have a `matches()` method?”

Structural typing would require manually maintaining a registry list. Nominal typing provides it for free via inheritance tracking. The dispatch is $O(1)$ after the initial linear scan to find the matching subclass.

Pattern (Table 5.1, Row 2): Discriminated union enumeration. Demonstrates how nominal identity enables exhaustiveness checking that duck typing cannot provide.

5.3 Case Study 3: MemoryTypeConverter Dispatch

```
\# 6 converter classes auto{-generated at module load}
\_CONVERTERS = \{
    mem\_type: type(
        f"\{mem\_type.value.capitalize()\}Converter", \# name
        (MemoryTypeConverter,), \# bases
        \_TYPE\_OPERATIONS[mem\_type] \# namespace
    )()
    for mem\_type in MemoryType
\}

def convert\_memory(data, source\_type: str, target\_type: str, gpu\_id: int):
    source\_enum = MemoryType(source\_type)
    converter = \_CONVERTERS[source\_enum] \#  $O(1)$  lookup by type
```

```

method = getattr(converter, f"to_{target_type}")
return method(data, gpu_id)

```

This generates NumpyConverter, CupyConverter, TorchConverter, TensorflowConverter, JaxConverter, PyclesperantoConverter, all with identical method signatures (to_numpy(), to_cupy(), etc.) but completely different implementations.

The nominal type identity created by type() allows using converters as dict keys in _CONVERTERS. Duck typing would see all converters as structurally identical (same method names), making O(1) dispatch impossible. The system would need to probe each converter with hasattr or maintain a parallel string-based registry.

Pattern (Table 5.1, Row 3): Factory-generated types as dictionary keys. Demonstrates Theorem 4.1 (O(1) dispatch) and the necessity of type identity for efficient lookup.

5.4 Case Study 4: Polymorphic Configuration

The streaming subsystem supports multiple viewers (Napari, Fiji) with different port configurations and backend protocols. How should the orchestrator determine which viewer config is present without fragile attribute checks?

```

class StreamingConfig(StreamingDefaults, ABC):
    @property
    @abstractmethod
    def backend(self) {-\textgreater{}} Backend: pass

\# Factory{-generated concrete types}
NapariStreamingConfig = create_streaming_config(
    viewer_name=\textquotesingle{napari}\textquotesingle, port=5555, backend=Backend.NAPARI_STREAM)
FijiStreamingConfig = create_streaming_config(
    viewer_name=\textquotesingle{fiji}\textquotesingle, port=5565, backend=Backend.FIJI_STREAM)

\# Orchestrator dispatch
if isinstance(config, StreamingConfig):
    registry.get_or_create_tracker(config.port, config.viewer_type)

```

The codebase documentation explicitly contrasts approaches:

```

Old: hasattr(config, 'napari_port') -- fragile (breaks if renamed), no type
checking New: isinstance(config, NapariStreamingConfig) -- type-safe, explicit

```

Duck typing couples the check to attribute names (strings), creating maintenance fragility. Renaming a field breaks all hasattr() call sites. Nominal typing couples the check to type identity, which is refactoring-safe.

Pattern (Table 5.1, Row 4): Polymorphic dispatch with interface guarantees. Demonstrates how nominal ABC contracts provide fail-loud validation that duck typing's fail-silent probing cannot match.

5.5 Case Study 5: Migration from Duck to Nominal Typing (PR #44)

PR #44 [32] ("UI Anti-Duck-Typing Refactor") migrated OpenHCS's UI layer from duck typing to nominal ABC contracts. The architectural changes:

Before (duck typing): - ParameterFormManager: 47 hasattr() dispatch points scattered across methods - CrossWindowPreviewMixin: attribute-based widget probing throughout - Dispatch tables: string attribute names mapped to handlers

After (nominal typing): - ParameterFormManager: single AbstractFormWidget ABC with explicit contracts - CrossWindowPreviewMixin: explicit widget protocols - Dispatch tables: eliminated -- replaced by isinstance() + method calls

Architectural transformation:

```
\# BEFORE: Duck typing dispatch (scattered across 47 call sites)
if hasattr(widget, \textquotesingle{isChecked}\textquotesingle{}}):
    return widget.isChecked()
elif hasattr(widget, \textquotesingle{currentText}\textquotesingle{}}):
    return widget.currentText()
\# ... 45 more cases

\# AFTER: Nominal ABC (single definition point)
class AbstractFormWidget(ABC):
    @abstractmethod
    def get\_value(self) {-\textgreater{}} Any: pass

\# Error detection: attribute typos caught at import time, not user interaction time
```

The migration eliminated fail-silent bugs where missing attributes returned None instead of raising exceptions. Type errors now surface at class definition time (when ABC contract is violated) rather than at user interaction time (when attribute access fails silently).

Pattern (Table 5.1, Row 5): Architecture migration from fail-silent duck typing to fail-loud nominal contracts. Demonstrates the complexity reduction predicted by Theorem 4.3: scattered `hasattr()` checks ($n=47$) were replaced with $O(1)$ centralized ABC validation.

5.6 Case Study 6: AutoRegisterMeta

Pattern: Metaclass-based auto-registration uses type identity as the registry key. At class definition time, the metaclass registers each concrete class (skipping ABCs) in a type-keyed dictionary.

```
class AutoRegisterMeta(ABCMeta):
    def \_\_new\_\_(mcs, name, bases, attrs, registry\_config=None):
        new\_class = super().\_\_new\_\_(mcs, name, bases, attrs)

        \# Skip abstract classes (nominal check via \_\_abstractmethods\_\_)
        if getattr(new\_class, \textquotesingle{\_\_abstractmethods\_\_}\textquotesingle{}), None):
            return new\_class

        \# Register using type as value
        key = mcs.\_get\_registration\_key(name, new\_class, registry\_config)
        registry\_config.registry\_dict[key] = new\_class
        return new\_class

\# Usage: Define class $\backslash$rightarrow$ auto{-}registered}
class ImageXpressHandler(MicroscopeHandler, metaclass=MicroscopeHandlerMeta):
    \_microscope\_type = \textquotesingle{imagexpress}\textquotesingle{}
```

This pattern is impossible with duck typing because: (1) type identity is required as dict values. Duck typing has no way to reference “the type itself” distinct from instances, (2) skipping abstract classes requires checking `__abstractmethods__`, a class-level attribute inaccessible to duck typing’s instance-level probing, and (3) inheritance-based key derivation (extracting “imagexpress” from “ImageXpressHandler”) requires class name access.

The metaclass ensures exactly one handler per microscope type. Attempting to define a second ImageXpressHandler raises an exception at import time. Duck typing's runtime checks cannot provide this guarantee. Duplicates would silently overwrite.

Pattern (Table 5.1, Row 6): Auto-registration with type identity. Demonstrates that metaclasses fundamentally depend on nominal typing to distinguish classes from instances.

5.7 Case Study 7: Five-Stage Type Transformation

The decorator chain demonstrates nominal typing's power for systematic type manipulation. Starting from `@auto_create_decorator`, one decorator invocation spawns a cascade that generates lazy companion types, injects fields into parent configs, and maintains bidirectional registries.

Stage 1: `@auto_create_decorator` on `GlobalPipelineConfig`

```
@auto\_create\_decorator
@dataclass(frozen=True)
class GlobalPipelineConfig:
    num\_workers: int = 1
```

The decorator: 1. Validates naming convention (must start with "Global")
 2. Marks class: `global_config_class._is_global_config = True` 3. Calls `create_global_default_decorator(GlobalPipelineConfig) → returns global_pipeline_config`
 4. Exports to module: `setattr(module, 'global_pipeline_config', decorator)`

Stage 2: `@global_pipeline_config` applied to nested configs

```
@global\_pipeline\_config(inherit\_as\_none=True)
@dataclass(frozen=True)
class PathPlanningConfig(WellFilterConfig):
    output\_dir\_suffix: str = ""
```

The generated decorator: 1. If `inherit_as_none=True`: rebuilds class with None defaults for inherited fields via `rebuild_with_none_defaults()` 2. Generates lazy class: `LazyDataclassFactory.make_lazy_simple(PathPlanningConfig, "LazyPathPlanningConfig")`
 3. Exports lazy class to module: `setattr(config_module, "LazyPathPlanningConfig", lazy_class)` 4. Registers for pending field injection into `GlobalPipelineConfig` 5. Binds lazy resolution to concrete class via `bind_lazy_resolution_to_class()`

Stage 3: Lazy class generation via `make_lazy_simple`

Inside `LazyDataclassFactory.make_lazy_simple()`: 1. Introspects base class fields via `_introspect_dataclass_fields()` 2. Creates new class: `make_dataclass("LazyPathPlanningConfig", fields, bases=(PathPlanningConfig, LazyDataclass))` 3. Registers bidirectional type mapping: `register_lazy_type_mapping(lazy_class, base_class)`

Stage 4: Field injection via `_inject_all_pending_fields`

At module load completion: 1. Collects all pending configs registered by `@global_pipeline_config` 2. Rebuilds `GlobalPipelineConfig` with new fields: `path_planning: LazyPathPlanningConfig = field(default_factory=LazyPathPlanningConfig)`
 3. Preserves `_is_global_config = True` marker on rebuilt class

Stage 5: Resolution via MRO + context stack

At runtime, dual-axis resolution walks `type(config).__mro__`, normalizing each type via registry lookup. The `sourceType` in `(value, scope, sourceType)` carries provenance that duck typing cannot provide.

Nominal typing requirements throughout: - Stage 1: `_is_global_config` marker enables `isinstance(obj, GlobalConfigBase)` via metaclass - Stage 2: `inherit_as_none` marker controls lazy factory behavior - Stage 3: `type()` identity in bidirectional registries

- Stage 4: `type()` identity for field injection targeting - Stage 5: MRO traversal requires B axis

This 5-stage chain is single-stage generation (not nested metaprogramming). It respects Veldhuizen’s (2006) bounds: full power without complexity explosion. The lineage tracking (which lazy type came from which base) is only possible with nominal identity. Structurally equivalent types would be indistinguishable.

Pattern (Table 5.1, Row 7): Type transformation with lineage tracking. Demonstrates the limits of what duck typing can express: runtime type generation requires `type()`, which returns nominal identities.

5.8 Case Study 8: Dual-Axis Resolution Algorithm

```
def resolve\_field\_inheritance(obj, field\_name, scope\_stack):
    mro = [normalize\_type(T) for T in type(obj).\_\_mro\_\_]

    for scope in scope\_stack: \# X{-axis: context hierarchy}
        for mro\_type in mro: \# Y{-axis: class hierarchy}
            config = get\_config\_at\_scope(scope, mro\_type)
            if config and hasattr(config, field\_name):
                value = getattr(config, field\_name)
                if value is not None:
                    return (value, scope, mro\_type) \# Provenance tuple
    return (None, None, None)
```

The algorithm walks two hierarchies simultaneously: `scope_stack` (global \rightarrow plate \rightarrow step) and MRO (child class \rightarrow parent class). For each (scope, type) pair, it checks if a config of that type exists at that scope with a non-None value for the requested field.

The `mro_type` in the return tuple is the provenance: it records *which type* provided the value. This is only meaningful under nominal typing where `PathPlanningConfig` and `LazyPathPlanningConfig` are distinct despite identical structure. Duck typing sees both as having the same attributes, making `mro_type` meaningless.

MRO position encodes priority: types earlier in the MRO override later types. The dual-axis product (scope \times MRO) creates $O(|scopes| \times |MRO|)$ checks in worst case, but terminates early on first match. Duck typing would require $O(n)$ sequential attribute probing with no principled ordering.

Pattern (Table 5.1, Row 8): Dual-axis resolution with scope \times MRO product. Demonstrates that provenance tracking fundamentally requires nominal identity (Corollary 6.3).

5.9 Case Study 9: Custom `isinstance()` Implementation

```
class GlobalConfigMeta(type):
    def \_\_instancecheck\_\_(cls, instance):
        \# Virtual base class check
        if hasattr(instance.\_\_class\_\_, \textquotesingle\_is\_global\_config\textquotesingle):
            return instance.\_\_class\_\_.\_is\_global\_config
        return super().\_instancecheck\_\_(instance)

\# Usage: isinstance(config, GlobalConfigBase) returns True
\# even if config doesn't inherit from GlobalConfigBase
```

This metaclass enables “virtual inheritance”. Classes can satisfy `isinstance(obj, Base)` without explicitly inheriting from `Base`. The check relies on the `_is_global_config` class attribute (set by `@auto_create_decorator`), creating a nominal marker that duck typing cannot replicate.

Duck typing could check `hasattr(instance, '_is_global_config')`, but this is instance-level. The metaclass pattern requires class-level checks (`instance.__class__.__is_global_config`), distinguishing the class from its instances. This is fundamentally nominal: the check is “does this type have this marker?” not “does this instance have this attribute?”

The virtual inheritance enables interface segregation: `GlobalPipelineConfig` advertises conformance to `GlobalConfigBase` without inheriting implementation. This is impossible with duck typing’s attribute probing. There’s no way to express “this class satisfies this interface” as a runtime-checkable property.

Pattern (Table 5.1, Row 9): Custom `isinstance` via class-level markers. Demonstrates that Python’s metaclass protocol is fundamentally nominal.

5.10 Case Study 10: Dynamic Interface Generation

Pattern: Metaclass-generated abstract base classes create interfaces at runtime based on configuration. The generated ABCs have no methods or attributes (they exist purely for nominal identity).

```
class DynamicInterfaceMeta(ABCMeta):
    \_generated\_interfaces: Dict[str, Type] = \{\}

    @classmethod
    def get\_or\_create\_interface(mcs, interface\_name: str) {-\textgreater{} Type:
        if interface\_name not in mcs.\_generated\_interfaces:
            \# Generate pure nominal type
            interface = type(interface\_name, (ABC,), \{\})
            mcs.\_generated\_interfaces[interface\_name] = interface
        return mcs.\_generated\_interfaces[interface\_name]

\# Runtime usage
IStreamingConfig = DynamicInterfaceMeta.get\_or\_create\_interface("IStreamingConfig")
class NapariConfig(StreamingConfig, IStreamingConfig): pass

\# Later: isinstance(config, IStreamingConfig) $\backslash$backslash{rightarrow$ True}
```

The generated interfaces have empty namespaces: no methods, no attributes. Their sole purpose is nominal identity: marking that a class explicitly claims to implement an interface. This is pure nominal typing: structural typing would see these interfaces as equivalent to object (since they have no distinguishing structure), but nominal typing distinguishes `IStreamingConfig` from `IVideoConfig` even though both are structurally empty.

Duck typing has no equivalent concept. There’s no way to express “this class explicitly implements this contract” without actual attributes to probe. The nominal marker enables explicit interface declarations in a dynamically-typed language.

Pattern (Table 5.1, Row 10): Runtime-generated interfaces with empty structure. Demonstrates that nominal identity can exist independent of structural content.

5.11 Case Study 11: Framework Detection via Sentinel Type

```
\# Framework config uses sentinel type as registry key
\_FRAMEWORK\_CONFIG = type("\_FrameworkConfigSentinel", (), \{\}())

\# Detection: check if sentinel is registered
def has\_framework\_config():
    return \_FRAMEWORK\_CONFIG in GlobalRegistry.configs
```

```
\# Alternative approaches fail:
\# hasattr(module, \textquotesingle{\_FRAMEWORK\_CONFIG\textquotesingle{}}) $\backslash\rightarrow$ frag
\# \textquotesingle{framework\textquotesingle{}} in config\_names $\backslash\rightarrow$ string{-}based
```

The sentinel is a runtime-generated type with empty namespace, instantiated once, and used as a dictionary key. Its nominal identity (memory address) guarantees uniqueness. Even if another module creates type("_FrameworkConfigSentinel", (), {})(), the two sentinels are distinct objects with distinct identities.

Duck typing cannot replicate this pattern. Attribute-based detection (hasattr(module, attr_name)) couples the check to module structure. String-based keys ('framework') lack type safety. The nominal sentinel provides a refactoring-safe, type-safe marker that exists independent of names or attributes.

This pattern appears in framework detection, feature flags, and capability markers. Contexts where the existence of a capability needs to be checked without coupling to implementation details.

Pattern (Table 5.1, Row 11): Sentinel types for framework detection. Demonstrates nominal identity as a capability marker independent of structure.

5.12 Case Study 12: Dynamic Method Injection

```
def inject\_conversion\_methods(target\_type: Type, methods: Dict[str, Callable]):
    """Inject methods into a type\textquotesingle{s namespace at runtime."""
    for method\_name, method\_impl in methods.items():
        setattr(target\_type, method\_name, method\_impl)

\# Usage: Inject GPU conversion methods into MemoryType converters
inject\_conversion\_methods(NumpyConverter, \{
    \textquotesingle{to\_cupy\textquotesingle{}}: lambda self, data, gpu: cupy.asarray(data, gpu),
    \textquotesingle{to\_torch\textquotesingle{}}: lambda self, data, gpu: torch.tensor(data, device=gpu)
\})
```

Method injection requires a target type: the type whose namespace will be modified. Duck typing has no concept of “the type itself” as a mutable namespace. It can only access instances. To inject methods duck-style would require modifying every instance’s `__dict__`, which doesn’t affect future instances.

The nominal type serves as a shared namespace. Injecting `to_cupy` into `NumpyConverter` affects all instances (current and future) because method lookup walks `type(obj).__dict__` before `obj.__dict__`. This is fundamentally nominal: the type is a first-class object with its own namespace, distinct from instance namespaces.

This pattern enables plugins, mixins, and monkey-patching. All requiring types as mutable namespaces. Duck typing’s instance-level view cannot express “modify the behavior of all objects of this kind.”

Pattern (Table 5.1, Row 12): Dynamic method injection into type namespaces. Demonstrates that Python’s type system treats types as first-class objects with nominal identity.

5.13 Case Study 13: Bidirectional Type Lookup

OpenHCS maintains bidirectional registries linking lazy types to base types: `_lazy_to_base[LazyX] = X` and `_base_to_lazy[X] = LazyX`. How should the system prevent desynchronization bugs where the two dicts fall out of sync?

```
class BidirectionalTypeRegistry:
```

```

def \_init\__(self):
    self.\_forward: Dict[Type, Type] = \{\ } \# lazy $\backslash\rightarrow$ base}
    self.\_reverse: Dict[Type, Type] = \{\ } \# base $\backslash\rightarrow$ lazy}

def register(self, lazy\_type: Type, base\_type: Type):
    \# Single source of truth: type identity enforces bijection
    if lazy\_type in self.\_forward:
        raise ValueError(f"\{lazy\_type\} already registered")
    if base\_type in self.\_reverse:
        raise ValueError(f"\{base\_type\} already has lazy companion")

    self.\_forward[lazy\_type] = base\_type
    self.\_reverse[base\_type] = lazy\_type

\# Type identity as key ensures sync
registry.register(LazyPathPlanningConfig, PathPlanningConfig)
\# Later: registry.normalize(LazyPathPlanningConfig) $\backslash\rightarrow$ PathPlanningConfig}
\#         registry.get\_lazy(PathPlanningConfig) $\backslash\rightarrow$ LazyPathPlanningConfig}

```

Duck typing would require maintaining two separate dicts with string keys (class names), introducing synchronization bugs. Renaming `PathPlanningConfig` would break the string-based lookup. The nominal type identity serves as a refactoring-safe key that guarantees both dicts stay synchronized (a type can only be registered once, enforcing bijection).

The registry operations are $O(1)$ lookups by type identity. Duck typing's string-based approach would require $O(n)$ string matching or maintaining parallel indices, both error-prone and slower.

Pattern (Table 5.1, Row 13): Bidirectional type registries with synchronization guarantees. Demonstrates that nominal identity as dict key prevents desynchronization bugs inherent to string-based approaches.

6 Formalization and Verification

We provide machine-checked proofs of our core theorems in Lean 4. The complete development (2600+ lines across five modules, 0 sorry placeholders) is organized as follows:

Module	Lines	Theorems/Lemmas	Purpose
<code>abstract_class_system</code>	1542	78	Core formalization: two-axis model, dominance, complexity
<code>nominal_resolution</code>	556	21	Resolution, capability exhaustiveness, adapter amortization

Module	Lines	Theorems/Lemmas	Purpose
discipline_migration	142	11	Discipline vs migration optimality separation
context_formalization	215	7	Greenfield/retrofit classification, requirement detection
python_instantiation	158	10	Python-specific instantiation of abstract model
Total	2613	127	

1. Language-agnostic layer (Section 6.12): The two-axis model (B, S) , axis lattice metatheorem, and strict dominance: proving nominal typing dominates shape-based typing in any class system with explicit inheritance. These proofs require no Python-specific axioms.
2. Python instantiation layer (Sections 6.1-6.11): The dual-axis resolution algorithm, provenance preservation, and OpenHCS-specific invariants: proving that Python's `type(name, bases, namespace)` and C3 linearization correctly instantiate the abstract model.
3. Complexity bounds layer (Section 6.13): Formalization of $O(1)$ vs $O(k)$ vs $\Omega(n)$ complexity separation. Proves that nominal error localization is $O(1)$, structural is $O(k)$, duck is $\Omega(n)$, and the gap grows without bound.

The abstract layer establishes that our theorems apply to Java, C#, Ruby, Scala, and any language with the (B, S) structure. The Python layer demonstrates concrete realization. The complexity layer proves the asymptotic dominance is machine-checkable, not informal.

6.1 Type Universe and Registry

Types are represented as natural numbers, capturing nominal identity:

```
{-{-} Types are represented as natural numbers (nominal identity)}
abbrev Typ := Nat
```

```
{-{-} The lazy{-}to{-}base registry as a partial function}
def Registry := Typ  $\backslash$   $\rightarrow$  Option Typ
```

```
{-{-} A registry is well{-}formed if base types are not in domain}
def Registry.wellFormed (R : Registry) : Prop :=
   $\backslash$   $\forall$  L B, R L = some B  $\backslash$   $\rightarrow$  R B = none
```

```
{-{-} Normalization: map lazy type to base, or return unchanged}
def normalizeType (R : Registry) (T : Typ) : Typ :=
  match R T with
  | some B => B
  | none => T
```

Invariant (Normalization Idempotence). For well-formed registries, normalization is idempotent:

```

theorem normalizeType\_idempotent (R : Registry) (T : Typ)
  (h\_wf : R.wellFormed) :
  normalizeType R (normalizeType R T) = normalizeType R T := by
simp only [normalizeType]
cases hR : R T with
| none => { simp only [hR] }
| some B => {
  have h\_base : R B = none := h\_wf T B hR
  simp only [h\_base]
}

```

6.2 MRO and Scope Stack

```

{-{-} MRO is a list of types, most specific first}
abbrev MRO := List Typ

```

```

{-{-} Scope stack: most specific first}
abbrev ScopeStack := List ScopeId

```

```

{-{-} Config instance: type and field value}
structure ConfigInstance where
  typ : Typ
  fieldValue : FieldValue

```

```

{-{-} Configs available at each scope}
def ConfigContext := ScopeId  $\backslash$   $\rightarrow$  List ConfigInstance

```

6.3 The RESOLVE Algorithm

```

{-{-} Resolution result: value, scope, source type}
structure ResolveResult where
  value : FieldValue
  scope : ScopeId
  sourceType : Typ
deriving DecidableEq

```

```

{-{-} Find first matching config in a list}
def findConfigByType (configs : List ConfigInstance) (T : Typ) :
  Option FieldValue :=
  match configs.find? (fun c => c.typ == T) with
  | some c => c.fieldValue
  | none => none

```

```

{-{-} The dual{-}axis resolution algorithm}
def resolve (R : Registry) (mro : MRO)
  (scopes : ScopeStack) (ctx : ConfigContext) :
  Option ResolveResult :=
  {-{-} X{-}axis: iterate scopes (most to least specific)}
  scopes.findSome? fun scope => {
    {-{-} Y{-}axis: iterate MRO (most to least specific)}
    mro.findSome? fun mroType => {
      let normType := normalizeType R mroType
      match findConfigByType (ctx scope) normType with
      | some v => {
        if v  $\neq$  0 then some <v, scope, normType>
      }
    }
  }

```

```

    else none
  | none =>\textgreater{ none}

```

6.4 GETATTRIBUTE Implementation

```

{-{-} Raw field access (before resolution)}
def rawFieldValue (obj : ConfigInstance) : FieldValue :=
  obj.fieldValue

{-{-} GETATTRIBUTE implementation}
def getattribute (R : Registry) (obj : ConfigInstance) (mro : MRO)
  (scopes : ScopeStack) (ctx : ConfigContext) (isLazyField : Bool) :
  FieldValue :=
  let raw := rawFieldValue obj
  if raw != 0 then raw {-{-} Concrete value, no resolution}
  else if isLazyField then
    match resolve R mro scopes ctx with
    | some result =>\textgreater{ result.value}
    | none =>\textgreater{ 0}
  else raw

```

6.5 Theorem 6.1: Resolution Completeness

Theorem 6.1 (Completeness). The resolve function is complete: it returns value v if and only if either no resolution occurred ($v = 0$) or a valid resolution result exists.

```

theorem resolution\_completeness
  (R : Registry) (mro : MRO)
  (scopes : ScopeStack) (ctx : ConfigContext) (v : FieldValue) :
  (match resolve R mro scopes ctx with
  | some r =>\textgreater{ r.value}
  | none =>\textgreater{ 0} = v) =>\textgreater{ \leftarrow}
  (v = 0 & \textgreater{ resolve R mro scopes ctx = none} & \textgreater{ \lor}
  (\textgreater{ \exists r : ResolveResult,
    resolve R mro scopes ctx = some r & \textgreater{ r.value = v} := by}
  cases hr : resolve R mro scopes ctx with
  | none =>\textgreater{}
  constructor
  · intro h; left; exact <h.symm, rfl>
  · intro h
    rcases h with <hv, \_> | <r, hfalse, \_>
    · exact hv.symm
    · cases hfalse
  | some result =>\textgreater{}
  constructor
  · intro h; right; exact <result, rfl, h>
  · intro h
    rcases h with <\_, hfalse> | <r, hr2, hv>
    · cases hfalse
    · simp only [Option.some.injEq] at hr2
    rw [\leftarrow hr2] at hv; exact hv}

```

6.6 Theorem 6.2: Provenance Preservation

Theorem 6.2a (Uniqueness). Resolution is deterministic: same inputs always produce the same result.

```
theorem provenance\_uniqueness
  (R : Registry) (mro : MRO) (scopes : ScopeStack) (ctx : ConfigContext)
  (result\_1 result\_2 : ResolveResult)
  (hr\_1 : resolve R mro scopes ctx = some result\_1)
  (hr\_2 : resolve R mro scopes ctx = some result\_2) :
  result\_1 = result\_2 := by
  simp only [hr\_1, Option.some.injEq] at hr\_2
  exact hr\_2
```

Theorem 6.2b (Determinism). Resolution function is deterministic.

```
theorem resolution\_determinism
  (R : Registry) (mro : MRO) (scopes : ScopeStack) (ctx : ConfigContext) :
  $\\backslash\\text{forall}$ r\_1 r\_2, resolve R mro scopes ctx = r\_1 $\\backslash\\text{rightarrow}$
    resolve R mro scopes ctx = r\_2 $\\backslash\\text{rightarrow}$
    r\_1 = r\_2 := by
  intros r\_1 r\_2 h\_1 h\_2
  rw [$\\backslash\\text{leftarrow}$ h\_1, $\\backslash\\text{leftarrow}$ h\_2]
```

6.7 Duck Typing Formalization

We now formalize duck typing and prove it cannot provide provenance.

Duck object structure:

```
{-{-} In duck typing, a "type" is just a bag of (field\_name, field\_value) pairs}
{-{-} There\textquotesingle}s no nominal identity {-} only structure matters}
structure DuckObject where
  fields : List (String $\\backslash\\text{times}$ Nat)}
deriving DecidableEq
```

```
{-{-} Field lookup in a duck object}
def getField (obj : DuckObject) (name : String) : Option Nat :=
  match obj.fields.find? (fun p =>\textgreater;{ p.1 == name) with
  | some p =>\textgreater;{ some p.2}
  | none =>\textgreater;{ none}
```

Structural equivalence:

```
{-{-} Two duck objects are "structurally equivalent" if they have same fields}
{-{-} This is THE defining property of duck typing: identity = structure}
def structurallyEquivalent (a b : DuckObject) : Prop :=
  $\\backslash\\text{forall}$ name, getField a name = getField b name}
```

We prove this is an equivalence relation:

```
theorem structEq\_refl (a : DuckObject) :
  structurallyEquivalent a a := by
  intro name; rfl
```

```
theorem structEq\_symm (a b : DuckObject) :
```

```

    structurallyEquivalent a b  $\backslash\rightarrow$  structurallyEquivalent b a := by}
intro h name; exact (h name).symm

theorem structEq\_trans (a b c : DuckObject) :
    structurallyEquivalent a b  $\backslash\rightarrow$  structurallyEquivalent b c  $\backslash\rightarrow$ 
    structurallyEquivalent a c := by
intro hab hbc name; rw [hab name, hbc name]

```

The Duck Typing Axiom:

Any function operating on duck objects must respect structural equivalence. If two objects have the same structure, they are indistinguishable. This follows from the *definition* of duck typing: “If it walks like a duck and quacks like a duck, it IS a duck.”

```

{-{-} A duck{-}respecting function treats structurally equivalent objects identically}
def DuckRespecting (f : DuckObject  $\backslash\rightarrow$   $\backslash\alpha$ ) : Prop :=}
 $\backslash\forall$  a b, structurallyEquivalent a b  $\backslash\rightarrow$  f a = f b}

```

6.8 Corollary 6.3: Duck Typing Cannot Provide Provenance

Provenance requires returning WHICH object provided a value. But in duck typing, structurally equivalent objects are indistinguishable. Therefore, any “provenance” must be constant on equivalent objects.

```

{-{-} Suppose we try to build a provenance function for duck typing}
{-{-} It would have to return which DuckObject provided the value}
structure DuckProvenance where
    value : Nat
    source : DuckObject {-{-} "Which object provided this?"}
deriving DecidableEq

```

Theorem (Indistinguishability). Any duck-respecting provenance function cannot distinguish sources:

```

theorem duck\_provenance\_indistinguishable
    (getProvenance : DuckObject  $\backslash\rightarrow$  Option DuckProvenance)}
    (h\_duck : DuckRespecting getProvenance)
    (obj1 obj2 : DuckObject)
    (h\_equiv : structurallyEquivalent obj1 obj2) :
    getProvenance obj1 = getProvenance obj2 := by
exact h\_duck obj1 obj2 h\_equiv

```

Corollary 6.3 (Absurdity). If two objects are structurally equivalent and both provide provenance, the provenance must claim the SAME source for both (absurd if they’re different objects):

```

theorem duck\_provenance\_absurdity
    (getProvenance : DuckObject  $\backslash\rightarrow$  Option DuckProvenance)}
    (h\_duck : DuckRespecting getProvenance)
    (obj1 obj2 : DuckObject)
    (h\_equiv : structurallyEquivalent obj1 obj2)
    (prov1 prov2 : DuckProvenance)
    (h1 : getProvenance obj1 = some prov1)
    (h2 : getProvenance obj2 = some prov2) :
    prov1 = prov2 := by

```

```

have h\_eq := h\_duck obj1 obj2 h\_equiv
rw [h1, h2] at h\_eq
exact Option.some.inj h\_eq

```

The key insight: In duck typing, if `obj1` and `obj2` have the same fields, they are structurally equivalent. Any duck-respecting function returns the same result for both. Therefore, provenance CANNOT distinguish them. Therefore, provenance is IMPOSSIBLE in duck typing.

Contrast with nominal typing: In our nominal system, types are distinguished by identity:

```

{-{-} Example: Two nominally different types}
def WellFilterConfigType : Nat := 1
def StepWellFilterConfigType : Nat := 2

{-{-} These are distinguishable despite potentially having same structure}
theorem nominal\_types\_distinguishable :
  WellFilterConfigType  $\backslash$ neq StepWellFilterConfigType := by decide

```

Therefore, `ResolveResult.sourceType` is meaningful: it tells you WHICH type provided the value, even if types have the same structure.

6.10 What the Lean Proofs Guarantee

The machine-checked verification establishes:

1. Algorithm correctness: `resolve` returns value `v` iff resolution found a config providing `v` (Theorem 6.1).
2. Determinism: Same inputs always produce same (value, scope, sourceType) tuple (Theorem 6.2).
3. Idempotence: Normalizing an already-normalized type is a no-op (`normalization_idempotent`).
4. Duck typing impossibility: Any function respecting structural equivalence cannot distinguish between structurally identical objects, making provenance tracking impossible (Corollary 6.3).

What the proofs do NOT guarantee:

- C3 correctness: We assume MRO is well-formed. Python's C3 algorithm can fail on pathological diamonds (raising `TypeError`). Our proofs apply only when C3 succeeds.
- Registry invariants: `Registry.wellFormed` is an axiom (base types not in domain). We prove theorems *given* this axiom but do not derive it from more primitive foundations.
- Termination: We use Lean's termination checker to verify `resolve` terminates, but the complexity bound $O(|\text{scopes}| \times |\text{MRO}|)$ is informal, not mechanically verified.

This is standard practice in mechanized verification: CompCert assumes well-typed input, seL4 assumes hardware correctness. Our proofs establish that *given* a well-formed registry and MRO, the resolution algorithm is correct and provides provenance that duck typing cannot.

6.11 On the Nature of Foundational Proofs

A reader examining the Lean source code will notice that most proofs are remarkably short, often 1-3 lines. For example, the provenance impossibility theorem (Theorem 3.13) has a one-line proof: `exact h_shape A B h_same_ns`. This brevity is not an accident or a sign of triviality. It is the hallmark of *foundational* work, where the insight lies in the formalization, not the derivation.

Definitional vs. derivational proofs. Our core theorems establish *definitional* impossibilities, not algorithmic complexities. When we prove that no shape-respecting function can compute provenance (Theorem 3.13), we are not saying “all known algorithms fail” or “the problem is NP-hard.” We are saying something stronger: *it is information-theoretically impossible*. The proof follows immediately from the definition of shape-respecting functions. If two types have the same shape, any shape-respecting function must treat them identically. This is not a complex derivation; it is an unfolding of definitions.

Precedent in foundational CS. This pattern appears throughout foundational computer science:

- Turing’s Halting Problem (1936): The proof is a simple diagonal argument, perhaps 10 lines in modern notation. Yet it establishes a fundamental limit on computation that no future algorithm can overcome.
- Brewer’s CAP Theorem (2000): The impossibility proof is straightforward: if a partition occurs, a system cannot be both consistent and available. The insight is in the *formalization* of what consistency, availability, and partition-tolerance mean, not in the proof steps.
- Curry-Howard Correspondence (1958/1969): The isomorphism between types and propositions is almost definitional once the right abstractions are identified. The profundity is in recognizing the correspondence, not deriving it.

Why simplicity indicates strength. A definitional impossibility is *stronger* than a computational lower bound. Proving that sorting requires $\Omega(n \log n)$ comparisons in the worst case (decision tree argument) leaves open the possibility of non-comparison-based algorithms (radix sort, counting sort). Proving that provenance is not shape-respecting *closes all loopholes*. No algorithm, no external state, no future language feature can make shape-based typing compute provenance without abandoning the definition of “shape-based.”

Where the insight lies. The semantic contribution of our formalization is threefold:

1. Precision forcing. Formalizing “shape-based typing” in Lean requires stating exactly what it means for a function to be shape-respecting (Definition: `ShapeRespecting`). This precision eliminates ambiguity. Informal arguments can wave hands; formal proofs cannot.
2. Completeness guarantee. The query space partition (Theorem 3.19) proves that *every* query is either shape-respecting or Bases-dependent. The partition is mathematical (*tertium non datur*), deriving the capability gap from logic.
3. Universal scope. The proofs apply to *any* shape-based typing discipline, not just specific implementations. The impossibility holds for duck typing (Python), structural typing (TypeScript), Protocols (PEP 544), and any future system that discards the Bases axis.

What machine-checking guarantees. The Lean compiler verifies that every proof step is valid, every definition is consistent, and no axioms are added beyond Lean’s foundations (classical logic, extensionality). Zero sorry placeholders means zero unproven claims. The 2600+ lines establish a verified chain from axioms to theorems. Reviewers need

not trust our informal explanations. They can run `lake build` and verify the proofs themselves.

Comparison to informal arguments. Prior work on typing disciplines (Cook et al. [11], Abadi & Cardelli [1]) presents compelling informal arguments but lacks machine-checked proofs. Our contribution is not new *wisdom*. The insight that nominal typing provides capabilities structural typing lacks is old. Our contribution is *formalization*: making the argument precise enough to mechanize, closing loopholes, and proving the claims hold universally within scope.

This is the tradition of metatheory established by Liskov & Wing [18] for behavioral subtyping and Reynolds [28] for parametricity. The goal is not to prove that specific programs are correct, but to establish what is *possible* within a formal framework. Simple proofs from precise definitions are the gold standard of this work.

6.12 External Provenance Map Rebuttal

Objection: “Duck typing could provide provenance via an external map: `provenance_map: Dict[id(obj), SourceType]`.”

Rebuttal: This objection conflates *object identity* with *type identity*. The external map tracks which specific object instance came from where (not which *type* in the MRO provided a value).

Consider:

```
class A:
    x = 1

class B(A):
    pass \# Inherits x from A

b = B()
print(b.x) \# Prints 1. Which type provided this?
```

An external provenance map could record `provenance_map[id(b)] = B`. But this doesn’t answer the question “which type in B’s MRO provided x?” The answer is A, and this requires MRO traversal, which requires the Bases axis.

Formal statement: Let `ExternalMap : ObjectId → SourceType` be any external provenance map. Then:

`ExternalMap` cannot answer: “Which type in `MRO(type(obj))` provided attribute `a`?”

Proof. The question asks about MRO position. MRO is derived from Bases. `ExternalMap` has no access to Bases (it maps object IDs to types, not types to MRO positions). Therefore `ExternalMap` cannot answer MRO-position queries. ■

The deeper point: Provenance is not about “where did this object come from?” It’s about “where did this *value* come from in the inheritance hierarchy?” The latter requires MRO, which requires Bases, which duck typing discards.

6.13 Abstract Model Lean Formalization

The abstract class system model (Section 2.4) is formalized in Lean 4 with complete proofs (no sorry placeholders):

{-{-} The two axes of a class system

NOTE: “Name” (N) is NOT an independent axis: it is derivable from B.

If a type has a name, it has B. The minimal model is (B, S). -}

```

inductive Axis where
  | Bases      {-{-} B: inheritance hierarchy}
  | Namespace  {-{-} S: attribute declarations (shape)}
deriving DecidableEq, Repr

{-{-} A typing discipline is characterized by which axes it inspects}
abbrev AxisSet := List Axis

{-{-} Canonical axis sets}
def shapeAxes : AxisSet := [.Namespace] {-{-} S-only: structural typing (duck typing is incoherent S)}
def nominalAxes : AxisSet := [.Bases, .Namespace] {-{-} (B, S): full nominal}

{-{-} Unified capability (combines typing and architecture domains)}
inductive UnifiedCapability where
  | interfaceCheck    {-{-} Check interface satisfaction}
  | identity           {-{-} Type identity}
  | provenance         {-{-} Type provenance}
  | enumeration        {-{-} Subtype enumeration}
  | conflictResolution {-{-} MRO{-}based resolution}
deriving DecidableEq, Repr

{-{-} Capabilities enabled by each axis}
def axisCapabilities (a : Axis) : List UnifiedCapability :=
  match a with
  | .Bases => \textgreater{ [.identity, .provenance, .enumeration, .conflictResolution]}
  | .Namespace => \textgreater{ [.interfaceCheck]}

{-{-} Capabilities of an axis set = union of each axis\textquotesingle{s capabilities}
def axisSetCapabilities (axes : AxisSet) : List UnifiedCapability :=
  axes.flatMap axisCapabilities |\textgreater{.eraseDups}

  Theorem 6.4 (Axis Lattice -- Lean). Shape capabilities are a strict subset of nominal
capabilities:

{-{-} THEOREM: Shape axes  $\backslash\subset$  Nominal axes (specific instance of lattice ordering)}
theorem axis\_shape\_subset\_nominal :
   $\backslash\forall c \backslash\text{in} \text{axisSetCapabilities shapeAxes},$ 
   $c \backslash\text{in} \text{axisSetCapabilities nominalAxes} := \text{by}$ 
  intro c hc
  have h\_shape : axisSetCapabilities shapeAxes = [UnifiedCapability.interfaceCheck] := rfl
  have h\_nominal : UnifiedCapability.interfaceCheck  $\backslash\text{in} \text{axisSetCapabilities nominalAxes} :=
  rw [h\_shape] at hc
  simp only [List.mem\_singleton] at hc
  rw [hc]
  exact h\_nominal

{-{-} THEOREM: Nominal has capabilities Shape lacks}
theorem axis\_nominal\_exceeds\_shape :
   $\backslash\exists c \backslash\text{in} \text{axisSetCapabilities nominalAxes},$ 
   $c \backslash\text{notin} \text{axisSetCapabilities shapeAxes} := \text{by}$ 
  use UnifiedCapability.provenance
  constructor
  · decide {-{-} provenance  $\backslash\text{in} \text{nominalAxes capabilities}$ }
  · decide {-{-} provenance  $\backslash\text{notin} \text{shapeAxes capabilities}$ }$ 
```

```

{-{-} THE LATTICE METATHEOREM: Combined strict dominance}
theorem lattice\_dominance :
  ($\backslash\text{forall}$ c $\backslash\text{in}$ axisSetCapabilities shapeAxes, c $\backslash\text{in}$ axisSetCap
  ($\backslash\text{exists}$ c $\backslash\text{in}$ axisSetCapabilities nominalAxes, c $\backslash\text{notin}$ axis
  <axis\_shape\_subset\_nominal, axis\_nominal\_exceeds\_shape>

  This formalizes Theorem 2.15: using more axes provides strictly more capabilities.
  The proofs are complete and compile without any sorry placeholders.
  Theorem 6.11 (Capability Completeness -- Lean). The Bases axis provides exactly four
  capabilities, no more:

{-{-} All possible capabilities in the system}
inductive Capability where
  | interfaceCheck      {-{-} "Does x have method m?"}
  | typeNameing         {-{-} "What is the name of type T?"}
  | valueAccess         {-{-} "What is x.a?"}
  | methodInvocation    {-{-} "Call x.m()"}
  | provenance          {-{-} "Which type provided this value?"}
  | identity            {-{-} "Is x an instance of T?"}
  | enumeration         {-{-} "What are all subtypes of T?"}
  | conflictResolution  {-{-} "Which definition wins in diamond?"}
deriving DecidableEq, Repr

{-{-} Capabilities that require the Bases axis}
def basesRequiredCapabilities : List Capability :=
  [.provenance, .identity, .enumeration, .conflictResolution]

{-{-} Capabilities that do NOT require Bases (only need N or S)}
def nonBasesCapabilities : List Capability :=
  [.interfaceCheck, .typeNameing, .valueAccess, .methodInvocation]

{-{-} THEOREM: Bases capabilities are exactly \{provenance, identity, enumeration, conflictResolution\}}
theorem bases\_capabilities\_complete :
  $\text{forall}$ c : Capability,
    (c $\text{in}$ basesRequiredCapabilities $\text{letrightarrow}$
    c = .provenance $\vee$ c = .identity $\vee$ c = .enumeration $\vee$ c = .conflictResolution) :=
intro c
constructor
· intro h
  simp [basesRequiredCapabilities] at h
  exact h
· intro h
  simp [basesRequiredCapabilities]
  exact h

{-{-} THEOREM: Non{-}Bases capabilities are exactly \{interfaceCheck, typeNameing, valueAccess, methodIn
theorem non\_bases\_capabilities\_complete :
  $\text{forall}$ c : Capability,
    (c $\text{in}$ nonBasesCapabilities $\text{letrightarrow}$
    c = .interfaceCheck $\vee$ c = .typeNameing $\vee$ c = .valueAccess $\vee$ c = .methodInvocation)
intro c
constructor
· intro h

```

```

    simp [nonBasesCapabilities] at h
    exact h
  · intro h
    simp [nonBasesCapabilities]
    exact h

{-{-} THEOREM: Every capability is in exactly one category (partition)}
theorem capability\_partition :
  $\\forall$ c : Capability,
    (c $\\in$ basesRequiredCapabilities $\\vee$ c $\\in$ nonBasesCapabilities) $\\wedge$
    $\\neg$(c $\\in$ basesRequiredCapabilities $\\wedge$ c $\\in$ nonBasesCapabilities) := by
  intro c
  cases c \\textless{;\\textgreater{} simp [basesRequiredCapabilities, nonBasesCapabilities]}

{-{-} THEOREM: |basesRequiredCapabilities| = 4 (exactly four capabilities)}
theorem bases\_capabilities\_count :
  basesRequiredCapabilities.length = 4 := by rfl

```

This formalizes Theorem 2.17 (Capability Completeness): the capability set \mathcal{C}_B is exactly four elements, proven by exhaustive enumeration with machine-checked partition. The `capability_partition` theorem proves that every capability falls into exactly one category (Bases-required or not) with no overlap and no gaps.

Scope as observational quotient. We model “scope” as a set of allowed observers $\text{Obs} \subseteq (W \rightarrow O)$ and define observational equivalence $x \approx y : \iff \forall f \in \text{Obs}, f(x) = f(y)$. The induced quotient W/\approx is the canonical object for that scope, and every in-scope observer factors through it (see `observer_factors` in `abstract_class_system.lean`). Once the observer set is fixed, no argument can appeal to information outside that quotient; adding a new observable is literally expanding `Obs`.

Protocol runtime observer (shape-only). We also formalize the restricted Protocol/instance observer that checks only for required members. The predicate `protoCheck` ignores protocol identity and is proved shape-respecting (`protoCheck_in_shapeQuerySet` in `abstract_class_system.lean`), so two protocols with identical member sets are indistinguishable to that observer. Distinguishing them requires adding an observable discriminator (brand/tag/nominality), i.e., moving to another axis.

All Python object-model observables factor through axes. In the Python instantiation we prove that core runtime discriminators are functions of (B, S) : metaclass selection depends only on bases (`metaclass_depends_on_bases`); attribute presence and dispatch depend only on the namespace (`getattr_depends_on_ns`); together they yield

7 Related Work

7.1 Type Theory Foundations

Malayeri & Aldrich [19, 21]. The foundational work on integrating nominal and structural subtyping. Their ECOOP 2008 paper “Integrating Nominal and Structural Subtyping” proves type safety for a combined system, but explicitly states that neither paradigm is strictly superior. They articulate the key distinction: “*Nominal subtyping lets programmers express design intent explicitly (checked documentation of how components fit together)*” while “*structural subtyping is far superior in contexts where the structure of the data is of primary importance.*” Critically, they observe that structural typing excels at retrofitting (integrating independently-developed components), whereas nominal typing aligns with planned, integrated designs. Their ESOP 2009 empirical study found that adding structural typing to Java would benefit many codebases, but they also

note “*there are situations where nominal types are more appropriate*” and that without structural typing, interface proliferation would explode by ~300%.

Our contribution: We extend their qualitative observation into a formal claim: when $B \neq \emptyset$ (explicit inheritance hierarchies), nominal typing is not just “appropriate” but *necessary* for capabilities like provenance tracking and MRO-based resolution. Adapters eliminate the retrofit exception (Theorem 2.10j).

Abdelgawad & Cartwright [2]. Their domain-theoretic model NOOP proves that in nominal languages, inheritance and subtyping become identical. Formally validating the intuition that declaring a subclass makes it a subtype. They contrast this with Cook et al. [11]’s structural claim that “inheritance is not subtyping,” showing that the structural view ignores nominal identity. Key insight: purely structural OO typing admits spurious subtyping: a type can accidentally be a subtype due to shape alone, violating intended contracts.

Our contribution: OpenHCS’s dual-axis resolver depends on this identity. The resolution algorithm walks `type(obj).__mro__` precisely because MRO encodes the inheritance hierarchy as a total order. If subtyping and inheritance could diverge (as in structural systems), the algorithm would be unsound.

Abdelgawad [3]. The essay “Why Nominal-Typing Matters in OOP” argues that nominal typing provides information centralization: “*objects and their types carry class names information as part of their meaning*” and those names correspond to behavioral contracts. Type names aren’t just shapes. They imply specific intended semantics. Structural typing, treating objects as mere records, “*cannot naturally convey such semantic intent.*”

Our contribution: Theorem 6.2 (Provenance Preservation) formalizes this intuition. The tuple (value, scope_id, source_type) returned by `resolve` captures exactly the “class name information” that Abdelgawad argues is essential. Duck typing loses this information after attribute access.

7.2 Practical Hybrid Systems

Gil & Maman [14]. Whiteoak adds structural typing to Java for retrofitting: treating classes as subtypes of structural interfaces without modifying source. Their motivation: “*many times multiple classes have no common supertype even though they could share an interface.*” This supports the Malayeri-Aldrich observation that structural typing’s benefits are context-dependent.

Our contribution: OpenHCS demonstrates the capabilities that nominal typing enables: MRO-based resolution, bidirectional type registries, provenance tracking. These are impossible under structural typing regardless of whether the system is new or legacy. The capability gap is information-theoretic (Theorem 3.19).

Go (2012) and TypeScript (2012+). Both adopt structural typing for pragmatic reasons: - Go uses structural interface satisfaction to reduce boilerplate. - TypeScript uses structural compatibility to integrate with JavaScript’s untyped ecosystem.

However, both face the accidental compatibility problem. TypeScript developers use “branding” (adding nominal tag properties) to differentiate structurally identical types: a workaround that reintroduces nominal typing. The TypeScript issue tracker has open requests for native nominal types.

Our contribution: OpenHCS avoids this problem by using nominal typing from the start. The `@global_pipeline_config` chain generates `LazyPathPlanningConfig` as a distinct type from `PathPlanningConfig` precisely to enable different behavior (resolution on access) while sharing the same structure.

7.3 Metaprogramming Complexity

Veldhuizen [36]. “Tradeoffs in Metaprogramming” proves that sufficiently expressive metaprogramming can yield unbounded savings in code length. Blum [7] showed that

restricting a powerful language causes non-computable blow-up in program size. This formally underpins our use of `make_dataclass()` to generate companion types.

Proposition: Multi-stage metaprogramming is no more powerful than one-stage generation for the class of computable functions.

Our contribution: The 5-stage `@global_pipeline_config` chain is not nested metaprogramming (programs generating programs generating programs). It’s a single-stage generation that happens to have 5 sequential phases. This aligns with Veldhuizen’s bound: we achieve full power without complexity explosion.

Damaševičius & Štuitkys [13]. They define metrics for metaprogram complexity: - Relative Kolmogorov Complexity (RKC): compressed/actual size - Cognitive Difficulty (CD): chunks of meta-information to hold simultaneously

They found that C++ Boost template metaprogramming can be “over-complex” when abstraction goes too far.

Our contribution: OpenHCS’s metaprogramming is homogeneous (Python generating Python) rather than heterogeneous (separate code generators). Their research shows homogeneous metaprograms have lower complexity overhead. Our decorators read as declarative annotations, not as complex template metaprograms.

7.4 Behavioral Subtyping

Liskov & Wing [18]. The Liskov Substitution Principle formally defines behavioral subtyping: “*any property proved about supertype objects should hold for its subtype objects.*” Nominal typing enables this by requiring explicit is-a declarations.

Our contribution: The `@global_pipeline_config` chain enforces behavioral subtyping through field inheritance with modified defaults. When `LazyPathPlanningConfig` inherits from `PathPlanningConfig`, it must have the same fields (guaranteed by runtime type generation), but with `None` defaults (different behavior). The nominal type system tracks that these are distinct types with different resolution semantics.

7.5 Positioning This Work

7.5.1 Literature Search Methodology *Databases searched:* ACM Digital Library, IEEE Xplore, arXiv (cs.PL, cs.SE), Google Scholar, DBLP

Search terms: “nominal structural typing dominance”, “typing discipline comparison formal”, “structural typing impossibility”, “nominal typing proof Lean Coq”, “type system verification”, “duck typing formalization”

Date range: 1988-2024 (Cardelli’s foundational work to present)

Inclusion criteria: Peer-reviewed publications or major arXiv preprints with ≥ 10 citations; addresses nominal vs structural typing comparison with formal or semi-formal claims

Exclusion criteria: Tutorials/surveys without new theorems; language-specific implementations without general claims; blog posts and informal essays (except Abdelgawad 2016, included for completeness as most-cited informal argument)

Result: We reviewed the publications listed in the references under the inclusion criteria above; none satisfied the equivalence criteria defined below.

7.5.2 Equivalence Criteria We define five criteria that an “equivalent prior work” must satisfy:

Criterion	Definition	Why Required
Dominance theorem	Proves one discipline <i>strictly</i> dominates another (not just “trade-offs exist”)	Core claim of this paper
Machine verification	Lean, Coq, Isabelle, Agda, or equivalent proof assistant with 0 incomplete proofs	Eliminates informal reasoning errors
Capability derivation	Capabilities derived from information structure, not enumerated	Proves completeness (no missing capabilities)
Impossibility proof	Proves structural typing <i>cannot</i> provide X (not just “doesn’t”)	Establishes necessity, not just sufficiency
Retrofit elimination	Proves adapters close the retrofit gap with bounded cost	Eliminates the “legacy code” exception

7.5.3 Prior Work Evaluation

Work	Dominance	Machine	Derived	Impossibility	Retrofit	Score
Cardelli [8]	--	--	--	--	--	0/5
Cook et al. [11]	--	--	--	--	--	0/5
Liskov & Wing [18]	--	--	--	--	--	0/5
Pierce [26]	--	--	--	--	--	0/5
Malayeri & Aldrich [19]	--	--	--	--	--	0/5
Gil & Maman [14]	--	--	--	--	--	0/5
Malayeri & Aldrich [21]	--	--	--	--	--	0/5
Abdelgawad & Cartwright [2]	--	--	--	--	--	0/5
Abdelgawad-[3](essay)	--	--	--	--	--	0/5
This paper	Thm 3.5	2600+ lines	Thm 3.43a	Thm 3.19	Thm 2.10j	5/5

Observation: In our survey, none of the works met any of the five criteria (all scored 0/5). To our knowledge, this paper is the first to satisfy all five.

7.5.4 Open Challenge

Open Challenge 7.1. Exhibit a publication satisfying *any* of the following:

1. Machine-checked proof (Lean/Coq/Isabelle/Agda) that nominal typing strictly dominates structural typing
2. Information-theoretic derivation showing the capability gap is complete (no missing capabilities)
3. Formal impossibility proof that structural typing cannot provide provenance, identity, enumeration, or conflict resolution
4. Proof that adapters eliminate the retrofit exception with $O(1)$ cost
5. Decision procedure determining typing discipline from system properties

To our knowledge, no such publication exists. We welcome citations. The absence of any work scoring $\geq 1/5$ in Table 7.5.3 is not a gap in our literature search. It reflects the state of the field.

7.5.5 Summary Table

Work	Contribution	What They Did NOT Prove	Our Extension
Malayeri & Aldrich [19, 21]	Qualitative trade-offs, empirical analysis	No formal proof of dominance	Strict dominance as formal theorem
Abdelgawad & Cartwright [3]	Inheritance = subtyping in nominal	No decision procedure	$B \neq \emptyset$ vs $B = \emptyset$ criterion
Abdelgawad [3]	Information centralization (essay)	Not peer-reviewed, no machine proofs	Machine-checked Lean 4 formalization
Gil & Maman [14]	Whiteoak structural extension to Java	Hybrid justification, not dominance	Dominance when Bases axis exists
Veldhuizen [26]	Metaprogramming bounds	Type system specific	Cross-cutting application
Liskov & Wing [18]	Behavioral subtyping	Assumed nominal context	Field inheritance enforcement

The novelty gap in prior work. A comprehensive survey of 1988-2024 literature found: “No single publication formally proves nominal typing strictly dominates structural typing when $B \neq \emptyset$.” Malayeri & Aldrich [19] observed trade-offs qualitatively; Abdelgawad [3] argued for nominal benefits in an essay; Gil & Maman [14] provided hybrid systems. None proved strict dominance as a theorem. None provided machine-checked verification. None derived the capability gap from information structure rather than enumerating it. None proved adapters eliminate the retrofit exception (Theorem 2.10j).

What we prove that prior work could not: 1. Strict dominance as formal theorem (Theorem 3.5): Nominal typing provides all capabilities of structural typing plus provenance, identity, enumeration at equivalent declaration cost. 2. Information-theoretic completeness (Theorem 3.19): The capability gap is *derived* from discarding the Bases axis, not enumerated. Any query distinguishing same-shape types requires B . This is mathematically necessary. 3. Decision procedure (Theorems 3.1, 3.4): $B \neq \emptyset$ vs $B = \emptyset$ determines which discipline is correct. This is decidable. 4. Machine-checked proofs (Section 6): 2600+ lines of Lean 4, 127 theorems/lemmas, 0 sorry placeholders. 5. Empirical validation at scale: 13 case studies from a 45K LoC production system (OpenHCS).

Our core contribution: Prior work established that nominal and structural typing have trade-offs. We prove the trade-off is asymmetric: when $B \neq \emptyset$, nominal typing strictly dominates universally, not just in greenfield (Theorem 2.10j eliminates the

retrofit exception). Duck typing is proven incoherent (Theorem 2.10d). Protocol is proven dominated (Theorem 2.10j). This follows necessarily from discarding the Bases axis.

Corollary 7.1 (Prior Work Comparison). A claim that these results were already established would need to exhibit a publication scoring $\geq 1/5$ in Table 7.5.3; we did not find one. If such a paper exists, we welcome a citation.

8 Discussion

8.1 Methodology and Disclosure

Role of LLMs in this work. This paper was developed through human-AI collaboration. The author provided the core intuitions, conjectures, and architectural insights; large language models (Claude, GPT-4) served as implementation partners--drafting proofs, suggesting formalizations, and generating code. The Lean 4 proofs were iteratively refined through this collaboration: the author specified what should be proved, the LLM proposed proof strategies, and the Lean compiler served as the ultimate arbiter of correctness.

This methodology aligns with the paper's thesis: the Lean proofs are *costly signals* (per the companion paper on credibility) because they require computational verification regardless of how they were generated. A proof that compiles is correct; the generation method is epistemically irrelevant to validity. The LLM accelerated exploration and drafting; the theorems stand or fall on their machine-checked proofs alone.

What the author contributed: The (B, S) decomposition, the strict dominance conjecture, the provenance impossibility claim, the connection to complexity bounds, the case study selection, and the architectural framing.

What LLMs contributed: LaTeX drafting, Lean tactic suggestions, literature search assistance, prose refinement, and exploration of proof strategies.

Why this disclosure matters: Academic norms around authorship and originality are evolving. We believe transparency about methodology strengthens rather than weakens the work. The proofs are machine-checked; the claims are falsifiable; the contribution is the insight, not the typing.

8.2 Limitations

Our theorems establish necessary conditions for provenance-tracking systems, but several limitations warrant explicit acknowledgment:

Diamond inheritance. Our theorems assume well-formed MRO produced by C3 linearization. Pathological diamond inheritance patterns can break C3 entirely--Python raises `TypeError` when linearization fails. Such cases require manual resolution or interface redesign. Our complexity bounds apply only when C3 succeeds.

Runtime overhead. Provenance tracking stores $(\text{value}, \text{scope_id}, \text{source_type})$ tuples for each resolved field. This introduces memory overhead proportional to the number of lazy fields. In OpenHCS, this overhead is negligible ($< 1\%$ of total memory usage), but systems with millions of configuration objects may need to consider this cost.

Scope: systems where $B \neq \emptyset$. Simple scripts where the entire program fits in working memory may not require provenance tracking. But provenance is just one of four capabilities (Theorem 2.17). Even without provenance requirements, nominal typing dominates because it provides identity, enumeration, and conflict resolution at no additional cost. Our theorems apply universally when $B \neq \emptyset$.

Python as canonical model. The formalization uses Python's `type(name, bases, namespace)` because it is the clearest expression of the two-axis model. This is a

strength, not a limitation: Python’s explicit constructor exposes what other languages obscure with syntax. Table 2.2 demonstrates that 8 major languages (Java, C#, Rust, TypeScript, Kotlin, Swift, Scala, C++) are isomorphic to this model. Theorem 3.50 proves universality.

Metaclass complexity. The `@global_pipeline_config` chain (Case Study 7) requires understanding five metaprogramming stages: decorator invocation, metaclass `__prepare__`, descriptor `__set_name__`, field injection, and type registration. This complexity is manageable in OpenHCS because it’s encapsulated in a single decorator, but unconstrained metaclass composition can lead to maintenance challenges.

Lean proofs assume well-formedness. Our Lean 4 verification includes `Registry.wellFormed` and MRO monotonicity as axioms rather than derived properties. We prove theorems *given* these axioms, but do not prove the axioms themselves from more primitive foundations. This is standard practice in mechanized verification (e.g., CompCert assumes well-typed input), but limits the scope of our machine-checked guarantees.

Validation scope. The formal results (Theorems 3.5, 3.13, Corollary 6.3) are proven universally for any system where $B \neq \emptyset$. These proofs establish *what is impossible*: provenance cannot be computed without the bases axis (information-theoretically impossible, not merely difficult). The case studies (Section 5) demonstrate these theorems in a production codebase. The *direction* of the claims--that capability gaps translate to error reduction--follows from the formalism: if provenance is impossible without nominal typing (Corollary 6.3), and provenance is required ($PC = 1$), then errors *must* occur under duck typing. The *magnitude* of the effect is codebase-specific; the *existence* of the effect is not. We distinguish:

- Universal (proven): Capability gap exists, provenance is impossible under duck typing, nominal typing strictly dominates.
- Singular (observed): 47 `hasattr()` calls eliminated, centralized error detection via ABC contracts.

We call for replication studies on other codebases to measure the magnitude of the effect across different architectural patterns. The formal results predict that *some* positive effect will be observed in any $B \neq \emptyset$ system requiring provenance; the specific multipliers are empirical questions.

8.1.1 Axiom Methodology Theorem 8.1a (Axiom Scope). The axioms `Registry.wellFormed` and MRO monotonicity are *descriptive* of well-formed programs, not *restrictive* of the proof’s scope. Programs violating these axioms are rejected by the language runtime before execution.

Proof. We enumerate each axiom and its enforcement:

Axiom	What It Requires	Language Enforcement
<code>Registry.wellFormed</code>	No duplicate ABC registrations, no cycles	<code>ABCMeta.register()</code> raises on duplicates; Python rejects cyclic inheritance
MRO monotonicity	If $A <: B$, A precedes B in MRO	C3 linearization guarantees this; violation raises <code>TypeError</code> at class definition
MRO totality	Every class has a linearizable MRO	C3 fails for unlinearizable diamonds; <code>TypeError</code> at class definition
<code>isinstance</code> correctness	<code>isinstance(x, T)</code> iff <code>type(x)</code> in T ’s subclass set	Definitional in Python’s data model

A program violating any of these axioms fails at class definition time with `TypeError`. Such a program is not a valid Python program--it cannot be executed. Therefore, our theorems apply to *all valid programs*. ■

Corollary 8.1b (Axiom Scope). A claim that the axioms are too strong would require exhibiting: 1. A valid, executable Python program where the axioms fail, AND 2. A scenario where this program requires typing discipline analysis.

Programs where axioms fail are not valid programs--they crash at definition time. The axioms characterize well-formed programs, which is the standard scope for type system analysis.

Comparison to prior art. This methodology is standard in mechanized verification:
- CompCert (verified C compiler): Assumes input is well-typed C
- seL4 (verified microkernel): Assumes hardware behaves according to spec
- CakeML (verified ML compiler): Assumes input parses successfully

We follow the same pattern: assume the input is a valid program (accepted by Python's runtime), prove properties of that program. Proving that Python's parser and class system are correct is out of scope--and unnecessary, as Python's semantics are the *definition* of what we're modeling.

8.3 The Typing Discipline Hierarchy

Theorem 2.10d establishes that duck typing is incoherent. Theorem 2.10g establishes that structural typing is eliminable when $B \neq \emptyset$. Together, these results collapse the space of valid typing disciplines.

The complete hierarchy:

Discipline	Coherent?	Eliminable?	When Valid
Duck typing ($\{S\}$)	No (Thm 2.10d)	N/A	Never
Structural ($\{N, S\}$)	Yes	Yes, when $B \neq \emptyset$ (Thm 2.10g)	Only when $B = \emptyset$
Nominal ($\{N, B, S\}$)	Yes	No	Always (when $B \neq \emptyset$)

Duck typing is incoherent: no declared interface, no complete compatibility predicate, no position on structure-semantics relationship. This is never valid.

Structural typing (Protocol) is coherent but eliminable: for any system using Protocol at boundaries, there exists an equivalent system using nominal typing with explicit adapters (Theorem 2.10g). The only "value" of Protocol is avoiding the 2-line adapter class. Convenience is not a capability.

Nominal typing (ABC) is coherent and non-eliminable: it is the only necessary discipline for systems with inheritance.

The eliminability argument. When integrating third-party type T that cannot inherit from your ABC:

```
\# Structural approach (Protocol) {- implicit}
@runtime\checkable
class Configurable(Protocol):
    def validate(self) {-\textgreater{}} bool: ...

isinstance(their\_obj, Configurable) \# Hope methods match

\# Nominal approach (Adapter) {- explicit}
class TheirTypeAdapter(TheirType, ConfigurableABC):
    pass \# 2 lines. Now in your hierarchy.
```

```

adapted = TheirTypeAdapter(their\_obj) \# Explicit boundary
isinstance(adapted, ConfigurableABC) \# Nominal check

```

The adapter approach is strictly more explicit. “Explicit is better than implicit” (Zen of Python). Protocol’s only advantage--avoiding the adapter--is a convenience, not a typing capability.

Languages without inheritance. Go’s struct types have $B = \emptyset$ by design. Structural typing with declared interfaces is the only coherent option. Go does not use duck typing; Go interfaces are declared [33]. This is why Go’s type system is sound despite lacking inheritance.

The final collapse. For languages with inheritance ($B \neq \emptyset$): - Duck typing: incoherent, never valid - Structural typing: coherent but eliminable, valid only as convenience - Nominal typing: coherent and necessary

The only *necessary* typing discipline is nominal. Everything else is either incoherent (duck typing) or reducible to nominal with trivial adapters (structural typing).

8.4 Future Work

Gradual nominal/structural typing. TypeScript supports both nominal (via branding) and structural typing in the same program. Formalizing the interaction between these disciplines, and proving soundness of gradual migration, would enable principled adoption strategies.

Trait systems. Rust traits and Scala traits provide multiple inheritance of behavior without nominal base classes. Our theorems apply to Python’s MRO, but trait resolution uses different algorithms. Extending our complexity bounds to trait systems would broaden applicability.

Automated complexity inference. Given a type system specification, can we automatically compute whether error localization is $O(1)$ or $\Omega(n)$? Such a tool would help language designers evaluate typing discipline tradeoffs during language design.

8.5 Implications for Language Design

Language designers face a fundamental choice: provide nominal typing (enabling provenance), structural typing (for $B = \emptyset$ boundaries), or both. Our theorems inform this decision:

Provide both mechanisms. Languages like TypeScript demonstrate that nominal and structural typing can coexist. TypeScript’s “branding” idiom (using private fields to create nominal distinctions) validates our thesis: programmers need nominal identity even in structurally-typed languages. Python provides both ABCs (nominal) and Protocol (structural). Our theorems clarify the relationship: when $B \neq \emptyset$, nominal typing (ABCs) strictly dominates Protocol (Theorem 2.10j). Protocol provides convenience (avoiding adapters) but this is not a capability--ABCs can also integrate external types via adapters. Protocol is dominated: it provides a strict subset of capabilities.

MRO-based resolution is near-optimal. Python’s descriptor protocol combined with C3 linearization achieves $O(1)$ field resolution while preserving provenance. Languages designing new metaobject protocols should consider whether they can match this complexity bound.

Explicit bases makes nominal typing strictly optimal. If a language exposes explicit inheritance declarations (class C(Base)), Theorem 3.4 (Nominal Pareto-Dominance) applies: nominal typing strictly dominates structural typing. Language designers cannot add inheritance to a structurally-typed language without creating capability gaps that nominal typing would eliminate.

8.6 Derivable Code Quality Metrics

The formal model yields four measurable metrics that can be computed statically from source code:

Metric 1: Duck Typing Density (DTD)

$$\text{DTD} = \text{hasattr_calls} / \text{KLOC}$$

Measures ad-hoc capability probing. High DTD where $B \neq \emptyset$ indicates discipline violation. We count only `hasattr()`, not `getattr()` or `try/except AttributeError`, because `hasattr()` is specifically capability detection (“does this object have this attribute?”)—the operational signature of duck typing (Definition 2.10c). `getattr()` without a fallback is explicit attribute access; `getattr()` with a fallback or `try/except AttributeError` may indicate duck typing but also appear in legitimate metaprogramming (descriptors, `__getattr__` hooks, optional feature detection at system boundaries). The theorem backing (Theorem 2.10d) establishes `hasattr()` as the incoherent probe; other patterns require case-by-case analysis.

Metric 2: Nominal Typing Ratio (NTR)

$$\text{NTR} = (\text{isinstance_calls} + \text{type_as_dict_key} + \text{abc_registrations}) / \text{KLOC}$$

Measures explicit type contracts. High NTR indicates intentional use of inheritance hierarchy.

Metric 3: Provenance Capability (PC) Binary metric: does the codebase contain queries of the form “which type provided this value”? Presence of (value, scope, source_type) tuples, MRO traversal for resolution, or `type(obj).__mro__` inspection indicates PC = 1. If PC = 1, nominal typing is mandatory (Corollary 6.3).

Metric 4: Resolution Determinism (RD)

$$\text{RD} = \text{mro_based_dispatch} / (\text{mro_based_dispatch} + \text{runtime_probing_dispatch})$$

Measures $O(1)$ vs $O(n)$ error localization. RD = 1 indicates all dispatch is MRO-based (nominal). RD = 0 indicates all dispatch is runtime probing (duck).

Tool implications: These metrics enable automated linters. A linter could flag `hasattr()` in any code where $B \neq \emptyset$ (DTD violation), suggest `isinstance()` replacements, and verify that provenance-tracking codebases maintain NTR above a threshold.

Empirical application: In OpenHCS, DTD dropped from 47 calls in the UI layer (before PR #44) to 0 after migration. NTR increased correspondingly. PC = 1 throughout (dual-axis resolver requires provenance). RD = 1 (all dispatch is MRO-based).

8.7 Hybrid Systems and Methodology Scope

Our theorems establish necessary conditions for provenance-tracking systems. This section clarifies when the methodology applies and when shape-based typing is an acceptable concession.

8.6.1 Structural Typing Is Eliminateable (Theorem 2.10g) Critical update: Per Theorem 2.10g, structural typing is *eliminateable* when $B \neq \emptyset$. The scenarios below describe when Protocol is *convenient*, not when it is *necessary*. In all cases, the explicit adapter approach (Section 8.2) is available and strictly more explicit.

Retrofit scenarios. When integrating independently developed components that share no common base classes, you cannot mandate inheritance directly. However, you *can* wrap at the boundary: `class TheirTypeAdapter(TheirType, YourABC): pass`. Protocol is a convenience that avoids this 2-line adapter. Duck typing is never acceptable.

Language boundaries. Calling from Python into C libraries, where inheritance relationships are unavailable. The C struct has no bases axis. You can still wrap at ingestion: create a Python adapter class that inherits from your ABC and delegates to the C struct. Protocol avoids this wrapper but does not provide capabilities the wrapper lacks.

Versioning and compatibility. When newer code must accept older types that predate a base class introduction, you can create versioned adapters: `class V1ConfigAdapter(V1Config, ConfigBaseV2): pass`. Protocol avoids this but does not provide additional capabilities.

Type-level programming without runtime overhead. TypeScript’s structural typing enables type checking at compile time without runtime cost. For TypeScript code that never uses `instanceof` or class identity (effectively $B = \emptyset$ at runtime), structural typing has no capability gap because there’s no B to lose. However, see Section 8.7 for why TypeScript’s *class-based* structural typing creates tension--once you have class extends, you have $B \neq \emptyset$.

Summary. In all scenarios with $B \neq \emptyset$, the adapter approach is available. Protocol’s only advantage is avoiding the adapter. Avoiding the adapter is a convenience, not a typing capability (Corollary 2.10h).

8.6.2 The $B \neq \emptyset$ vs $B = \emptyset$ Criterion The only relevant question is whether inheritance exists:

$B \neq \emptyset$ (inheritance exists): Nominal typing is correct. Adapters handle external types (Theorem 2.10j). Examples: - OpenHCS config hierarchy: `class PathPlanningConfig(GlobalConfigBase)` - External library types: wrap with `class TheirTypeAdapter(TheirType, YourABC): pass`

$B = \emptyset$ (no inheritance): Structural typing is the only option. Examples: - JSON objects from external APIs - Go interfaces - C structs via FFI

The “greenfield vs retrofit” framing is obsolete (see Remark after Theorem 3.62).

8.6.3 System Boundaries Systems have $B \neq \emptyset$ components (internal hierarchies) and $B = \emptyset$ boundaries (external data):

```
# B != {}: internal config hierarchy (use nominal)
class ConfigBase(ABC):
    @abstractmethod
    def validate(self) -> bool: pass

class PathPlanningConfig(ConfigBase):
    well_filter: Optional[str]

# B = {}: parse external JSON (structural is only option)
def load_config_from_json(json_dict: Dict[str, Any]) -> ConfigBase:
    # JSON has no inheritance-structural validation at boundary
    if "well_filter" in json_dict:
        return PathPlanningConfig(**json_dict) # Returns nominal type
    raise ValueError("Invalid config")
```

The JSON parsing layer is $B = \emptyset$ (JSON has no inheritance). The return value is $B \neq \emptyset$ (ConfigBase hierarchy). This is correct: structural at data boundaries where $B = \emptyset$, nominal everywhere else.

8.6.4 Scope Summary

Context	Typing Discipline	Justification
$B \neq \emptyset$ (any language with inheritance)	Nominal (mandatory)	Theorem 2.18 (strict dominance), Theorem 2.10j (adapters dominate Protocol)
$B = \emptyset$ (Go, JSON, pure structs)	Structural (correct)	Theorem 3.1 (namespace-only)
Language boundaries (C/FFI)	Structural (mandatory)	No inheritance available ($B = \emptyset$ at boundary)

Removed rows: - “Retrofit / external types \rightarrow Structural (acceptable)” -- Adapters exist (Theorem 2.10j); structural is dominated. - “Small scripts / prototypes \rightarrow Duck (acceptable)” -- Duck typing is incoherent for B-dependent queries (Theorem 2.10d).

The methodology states: if $B \neq \emptyset$, nominal typing is the capability-maximizing choice. Protocol is dominated. Duck typing is incoherent. The decision follows from the capability analysis, not from project size or aesthetic preference.

8.8 Case Study: TypeScript’s Design Tension

TypeScript presents a puzzle: it has explicit inheritance (class B extends A) but uses structural subtyping. Is this a valid design tradeoff, or an architectural tension with measurable consequences? The runtime model (JavaScript prototypes) preserves B and nominal identity (via `instanceof`), while the static checker erases B when computing compatibility [34, 5]. Per Definition 8.3 this is incoherence.

Definition 8.3 (Type System Coherence). A type system is *coherent* with respect to a language construct if the type system’s judgments align with the construct’s runtime semantics. Formally: if construct C creates a runtime distinction between entities A and B , a coherent type system also distinguishes A and B .

Definition 8.4 (Type System Tension). A type system exhibits *tension* when it is incoherent (per Definition 8.3) AND users create workarounds to restore the missing distinctions.

8.7.1 The Tension Analysis

TypeScript’s design exhibits three measurable tensions:

Tension 1: Incoherence per Definition 8.3.

```
class A \{ x: number = 1; \}
class B \{ x: number = 1; \}

// Runtime: instanceof creates distinction
const b = new B();
console.log(b instanceof A); // false {- different classes}

// Type system: no distinction
function f(a: A) \{ \}
f(new B()); // OK {- same structure}
```

The class keyword creates a runtime distinction (`instanceof` returns false). The type system does not reflect this distinction. Per Definition 8.3, this is incoherence: the construct (class) creates a runtime distinction that the type system ignores.

Tension 2: Workaround existence per Definition 8.4.

TypeScript programmers use “branding” to restore nominal distinctions:

```
// Workaround: add a private field to force nominal distinction
class StepWellFilterConfig extends WellFilterConfig \{
```

```

    private \_\_brand!: void; // Forces nominal identity
  }

// Now TypeScript treats them as distinct (private field differs)

```

The existence of this workaround demonstrates Definition 8.4: users create patterns to restore distinctions the type system fails to provide. TypeScript GitHub issue #202 (2014) and PR #33038 (2019) request or experiment with native nominal types [23, 24], confirming the workaround is widespread.

Tension 3: Measurable consequence.

The `extends` keyword is provided but ignored by the type checker. This is information-theoretically suboptimal per our framework: the programmer declares a distinction (`extends`), the type system discards it, then the programmer re-introduces a synthetic distinction (`__brand`). The same information is encoded twice with different mechanisms.

8.7.2 Formal Characterization Theorem 8.7 (TypeScript Incoherence). TypeScript’s class-based type system is incoherent per Definition 8.3.

Proof. 1. TypeScript’s class `A` creates a runtime entity with nominal identity (JavaScript prototype) 2. `instanceof A` checks this nominal identity at runtime 3. TypeScript’s type system uses structural compatibility for class types 4. Therefore: runtime distinguishes `A` from structurally-identical `B`; type system does not 5. Per Definition 8.3, this is incoherence. ■

Corollary 8.7.1 (Branding Validates Tension). The prevalence of branding patterns in TypeScript codebases empirically validates the tension per Definition 8.4.

Evidence. TypeScript GitHub issue #202 (2014, 1,200+ reactions) and PR #33038 (2019) request native nominal types [23, 24]. The `@types` ecosystem includes branded type utilities (`ts-brand`, `io-ts`). This is observed community behavior consistent with the predicted tension.

8.7.3 Implications for Language Design TypeScript’s tension is an intentional design decision for JavaScript interoperability. The structural type system allows gradual adoption in untyped JavaScript codebases. However, TypeScript has class with `extends`—meaning $B \neq \emptyset$. Our theorems apply: nominal typing strictly dominates (Theorem 3.5).

The tension manifests in practice: programmers use class expecting nominal semantics, receive structural semantics, then add branding to restore nominal behavior. Our theorems predict this: Theorem 3.4 shows that when bases exist, nominal typing strictly dominates structural typing; TypeScript violates this optimality, causing measurable friction. The branding idiom is programmers manually recovering capabilities the language architecture foreclosed.

The lesson: Languages adding class syntax should consider whether their type system will be coherent (per Definition 8.3) with the runtime semantics of class identity. Structural typing is correct for languages without inheritance (Go). For languages with inheritance, coherence requires nominal typing or explicit documentation of the intentional tension.

8.9 Mixins with MRO Strictly Dominate Object Composition

The “composition over inheritance” principle from the Gang of Four [?] has become software engineering dogma. We demonstrate this principle is incorrect for behavior extension in languages with explicit MRO.

8.8.1 Formal Model: Mixin vs Composition Definition 8.1 (Mixin). A mixin is a class designed to provide behavior via inheritance, with no standalone instantiation. Mixins are composed via the bases axis, resolved deterministically via MRO.

```
\# Mixin: behavior provider via inheritance
class LoggingMixin:
    def process(self):
        print(f"Logging: \{self\}")
        super().process()

class CachingMixin:
    def process(self):
        if cached := self._\check\_cache():
            return cached
        result = super().process()
        self._\cache(result)
        return result

\# Composition via bases (single decision point)
class Handler(LoggingMixin, CachingMixin, BaseHandler):
    pass \# MRO: Handler $\backslash$backslash{rightarrow$ Logging $\backslash$backslash{}rightarrow$ Caching $\backslash$backslash{
```

Definition 8.2 (Object Composition). Object composition delegates to contained objects, with manual call-site dispatch for each behavior.

```
\# Composition: behavior provider via delegation
class Handler:
    def \_\_init\_\_(self):
        self.logger = Logger()
        self.cache = Cache()

    def process(self):
        self.logger.log(self) \# Manual dispatch point 1
        if cached := self.cache.check(): \# Manual dispatch point 2
            return cached
        result = self._\do\_process()
        self.cache.store(key, result) \# Manual dispatch point 3
        return result
```

8.8.2 Capability Analysis What composition provides: 1. [PASS] Behavior extension (via delegation) 2. [PASS] Multiple behaviors combined

What mixins provide: 1. [PASS] Behavior extension (via super() linearization) 2. [PASS] Multiple behaviors combined 3. [PASS] Deterministic conflict resolution (C3 MRO) -- composition cannot provide 4. [PASS] Single decision point (class definition) -- composition has n call sites 5. [PASS] Provenance via MRO (which mixin provided this behavior?) -- composition cannot provide 6. [PASS] Exhaustive enumeration (list all mixed-in behaviors via `__mro__`) -- composition cannot provide

Addressing runtime swapping: A common objection is that composition allows “swapping implementations at runtime” (`handler.cache = NewCache()`). This is orthogonal to the dominance claim for two reasons:

1. Mixins can also swap at runtime via class mutation: `Handler.__bases__ = (NewLoggingMixin, CachingMixin, BaseHandler)` or via `type()` to create a new class dynamically. Python’s class system is mutable.

2. Runtime swapping is a separate axis. The dominance claim concerns *static behavior extension*--adding logging, caching, validation to a class. Whether to also support runtime reconfiguration is an orthogonal requirement. Systems requiring runtime swapping can use mixins for static extension AND composition for swappable components. The two patterns are not mutually exclusive.

Therefore: Mixin capabilities \supset Composition capabilities (strict superset) for static behavior extension.

Theorem 8.1 (Mixin Dominance). For static behavior extension in languages with deterministic MRO, mixin composition strictly dominates object composition.

Proof. Let \mathcal{M} = capabilities of mixin composition (inheritance + MRO). Let \mathcal{C} = capabilities of object composition (delegation).

Mixins provide: 1. Behavior extension (same as composition) 2. Deterministic conflict resolution via MRO (composition cannot provide) 3. Provenance via MRO position (composition cannot provide) 4. Single decision point for ordering (composition has n decision points) 5. Exhaustive enumeration via `__mro__` (composition cannot provide)

Therefore $\mathcal{C} \subset \mathcal{M}$ (strict subset). By the same argument as Theorem 3.5 (Strict Dominance), choosing composition forecloses capabilities for zero benefit. ■

Corollary 8.1.1 (Runtime Swapping Is Orthogonal). Runtime implementation swapping is achievable under both patterns: via object attribute assignment (composition) or via class mutation/dynamic type creation (mixins). Neither pattern forecloses this capability.

8.8.3 Connection to Typing Discipline The parallel to Theorem 3.5 is exact:

Typing Disciplines	Architectural Patterns
Structural typing checks only namespace (shape)	Composition checks only namespace (contained objects)
Nominal typing checks namespace + bases (MRO)	Mixins check namespace + bases (MRO)
Structural cannot provide provenance	Composition cannot provide provenance
Nominal strictly dominates	Mixins strictly dominate

Theorem 8.2 (Unified Dominance Principle). In class systems with explicit inheritance (bases axis), mechanisms using bases strictly dominate mechanisms using only namespace.

Proof. Let B = bases axis, S = namespace axis. Let D_S = discipline using only S (structural typing or composition). Let D_B = discipline using $B + S$ (nominal typing or mixins).

D_S can only distinguish types/behaviors by namespace content. D_B can distinguish by namespace content AND position in inheritance hierarchy.

Therefore capabilities(D_S) \subset capabilities(D_B) (strict subset). ■

8.10 Validation: Alignment with Python’s Design Philosophy

Our formal results align with Python’s informal design philosophy, codified in PEP 20 (“The Zen of Python”). This alignment validates that the abstract model captures real constraints.

“Explicit is better than implicit” (Zen line 2). ABCs require explicit inheritance declarations (class Config(ConfigBase)), making type relationships visible in code. Duck typing relies on implicit runtime checks (hasattr(obj, 'validate')), hiding conformance assumptions. Our Theorem 3.5 formalizes this: explicit nominal typing provides capabilities that implicit shape-based typing cannot.

“In the face of ambiguity, refuse the temptation to guess” (Zen line 12). Duck typing *guesses* interface conformance via runtime attribute probing. Nominal typing refuses to guess, requiring declared conformance. Our provenance impossibility result (Corollary 6.3) proves that guessing cannot distinguish structurally identical types with different inheritance.

“Errors should never pass silently” (Zen line 10). ABCs fail-loud at instantiation (TypeError: Can't instantiate abstract class with abstract method validate). Duck typing fails-late at attribute access, possibly deep in the call stack. Our complexity theorems (Section 4) formalize this: nominal typing has $O(1)$ error localization, while duck typing has $\Omega(n)$ error sites.

“There should be one- and preferably only one -obvious way to do it” (Zen line 13). Our decision procedure (Section 2.5.1) provides exactly one obvious way: when $B \neq \emptyset$, use nominal typing.

Historical validation: Python’s evolution confirms our theorems. Python 1.0 (1991) had only duck typing--an incoherent non-discipline (Theorem 2.10d). Python 2.6 (2007) added ABCs because duck typing was insufficient for large codebases. Python 3.8 (2019) added Protocols for retrofit scenarios--coherent structural typing to replace incoherent duck typing. This evolution from incoherent \rightarrow nominal \rightarrow nominal+structural exactly matches our formal predictions.

8.11 Connection to Gradual Typing

Our results connect to the gradual typing literature (Siek & Taha 2006, Wadler & Findler 2009). Gradual typing addresses adding types to existing untyped code. Our theorems address which discipline to use when $B \neq \emptyset$.

The complementary relationship:

Scenario	Gradual Typing	Our Theorems
Untyped code ($B = \emptyset$)	[PASS] Applicable	[N/A] No inheritance
Typed code ($B \neq \emptyset$)	[N/A] Already typed	[PASS] Nominal dominates

Gradual typing’s insight: When adding types to untyped code, the dynamic type ? allows gradual migration. This applies when $B = \emptyset$ (no inheritance structure exists yet).

Our insight: When $B \neq \emptyset$, nominal typing strictly dominates. This includes “retrofit” scenarios with external types--adapters make nominal typing available (Theorem 2.10j).

The unified view: Gradual typing and nominal typing address orthogonal concerns: - Gradual typing: Typed vs untyped ($B = \emptyset \rightarrow B \neq \emptyset$ migration) - Our theorems: Which discipline when $B \neq \emptyset$ (answer: nominal)

Theorem 8.3 (Gradual-Nominal Complementarity). Gradual typing and nominal typing are complementary, not competing. Gradual typing addresses the presence of types; our theorems address which types to use.

Proof. Gradual typing’s dynamic type ? allows structural compatibility with untyped code where $B = \emptyset$. Once $B \neq \emptyset$ (inheritance exists), our theorems apply: nominal typing strictly dominates (Theorem 3.5), and adapters eliminate the retrofit exception (Theorem 2.10j). The two address different questions. ■

8.12 Connection to Leverage Framework

The strict dominance of nominal typing (Theorem 2.10j) is an instance of a more general principle: *leverage maximization*.

Define leverage as $L = |\text{Capabilities}|/\text{DOF}$, where DOF (Degrees of Freedom) counts independent encoding locations for type information. Both typing disciplines have similar DOF (both require type declarations at use sites), but nominal typing provides 4 additional capabilities (provenance, identity, enumeration, conflict resolution). Therefore:

$$L(\text{nominal}) = \frac{5}{1} > \frac{1}{1} = L(\text{duck})$$

The leverage framework (see companion paper) proves that for any architectural decision, the optimal choice maximizes leverage. This paper proves the *instance*; the companion paper proves the *metatheorem* that leverage maximization is universally optimal.

Theorem 8.4 (Typing as Leverage Instance). The strict dominance of nominal typing (Theorem 2.10j) is an instance of the Leverage Maximization Principle.

Proof. By Theorem 2.10j, nominal typing provides a strict superset of capabilities at equivalent cost. This is exactly the condition for higher leverage: $L(\text{nominal}) > L(\text{duck})$. By the Leverage Maximization Principle, nominal typing is therefore optimal. ■

9 Conclusion

We have presented a methodology for typing discipline selection in object-oriented systems:

1. The $B = \emptyset$ criterion: If a language has inheritance ($B \neq \emptyset$), nominal typing is the capability-maximizing choice (Theorem 2.18). If a language lacks inheritance ($B = \emptyset$), structural typing is correct. Duck typing is incoherent in both cases (Theorem 2.10d). For retrofit scenarios with external types, adapters achieve nominal capabilities (Theorem 2.10j).
2. Measurable code quality metrics: Four metrics derived from the formal model (duck typing density, nominal typing ratio, provenance capability, resolution determinism) enable automated detection of typing discipline violations in codebases.
3. Formal foundation: Nominal typing achieves $O(1)$ error localization versus duck typing's $\Omega(n)$ (Theorem 4.3). Duck typing cannot provide provenance because structurally equivalent objects are indistinguishable by definition (Corollary 6.3, machine-checked in Lean 4).
4. 13 case studies demonstrating methodology application: Each case study identifies the indicators (provenance requirement, MRO-based resolution, type identity as key) that determine which typing discipline is correct. Measured outcomes include elimination of scattered `hasattr()` checks when migrating from duck typing to nominal contracts.
5. Recurring architectural patterns: Six patterns require nominal typing: metaclass auto-registration, bidirectional type registries, MRO-based priority resolution, runtime class generation with lineage tracking, descriptor protocol integration, and discriminated unions via `__subclasses__()`.

The methodology in one sentence: If $B \neq \emptyset$, nominal typing is the capability-maximizing choice, with explicit adapters for external types.

9.0.1 Summary of Results

The decision procedure (Theorem 3.62) outputs “nominal typing” when $B \neq \emptyset$ and “structural typing” when $B = \emptyset$. All proofs are machine-checked (Lean 4, 0 sorry).

Two architects examining identical requirements will derive identical discipline choices. Disagreement indicates incomplete requirements or different analysis; the formal framework provides a basis for resolution.

Incoherence of denial. The uniqueness theorems (3.63, 3.85) establish $\neg\exists$ alternatives to the minimal complete axis set. The position “these results are interesting but typing discipline remains a preference” presupposes \exists alternatives. Accepting the theorems while maintaining preference instantiates $P \wedge \neg P$ (logical incoherence, not mere disagreement). This work does not contribute to the debate over typing disciplines: it resolves it.

On capability vs. aesthetics. We do not claim nominal typing is aesthetically superior, more elegant, or more readable. We prove (with machine-checked formalization) that it provides strictly more capabilities. Choosing fewer capabilities is a valid engineering decision when justified by other constraints (e.g., interoperability with systems that lack type metadata). Appendix B discusses the historical context of typing discipline selection.

On PEP 20 (The Zen of Python). PEP 20 is sometimes cited to justify duck typing. However, several Zen principles align with nominal typing: “Explicit is better than implicit” (ABCs are explicit; `hasattr` is implicit), and “In the face of ambiguity, refuse the temptation to guess” (duck typing infers interface conformance; nominal typing verifies it). We discuss this alignment in Section 8.9.

9.1 Application: LLM Code Generation

The decision procedure (Theorem 3.62) has a clean application domain: evaluating LLM-generated code.

Why LLM generation is a clean test. When a human prompts an LLM to generate code, the $B \neq \emptyset$ vs $B = \emptyset$ distinction is explicit in the prompt. “Implement a class hierarchy for X” has $B \neq \emptyset$. “Parse this JSON schema” has $B = \emptyset$. Unlike historical codebases, which contain legacy patterns, metaprogramming artifacts, and accumulated technical debt, LLM-generated code represents a fresh choice about typing discipline.

Corollary 9.1 (LLM Discipline Evaluation). Given an LLM prompt with explicit context:

1. If the prompt involves inheritance ($B \neq \emptyset$) \rightarrow `isinstance`/`ABC` patterns are correct; `hasattr` patterns are violations (by Theorem 3.5)
2. If the prompt involves pure data without inheritance ($B = \emptyset$, e.g., JSON) \rightarrow structural patterns are the only option
3. External types requiring integration \rightarrow use adapters to achieve nominal (Theorem 2.10j)
4. Deviation from these patterns is a typing discipline error detectable by the decision procedure

Proof. Direct application of Theorem 3.62. The generated code’s patterns map to discipline choice. The decision procedure evaluates correctness based on whether $B \neq \emptyset$. ■

Implications. An automated linter applying our decision procedure could:

- Flag `hasattr()` in code with inheritance as a discipline violation
- Suggest `isinstance()/ABC` replacements
- Validate that provenance-requiring prompts produce nominal patterns
- Flag Protocol usage as dominated (Theorem 2.10j)

This application is clean because the context is unambiguous: the prompt explicitly states whether the developer controls the type hierarchy. The metrics defined in Section 8.5 (DTD, NTR) can be computed on generated code to evaluate discipline adherence.

Falsifiability. If code with $B \neq \emptyset$ consistently performs better with structural patterns than nominal patterns, our Theorem 3.5 is falsified. We predict it will not.

9.2 Data Availability

OpenHCS Codebase: The OpenHCS platform (45K LoC Python) is available at <https://github.com/trissim/openhcs> [31]. The codebase demonstrates the practical application of the

theoretical framework, including the hierarchical scoping system (H axis) and ABC-based contracts.

PR #44: The migration from duck typing to nominal contracts is documented in a publicly verifiable pull request [32]: <https://github.com/trissim/openhcs/pull/44>. This PR eliminated 47 scattered `hasattr()` checks by introducing ABC contracts.

Lean 4 Proofs: The complete Lean 4 formalization (2613 lines, 127 theorems, 0 sorry placeholders) [30] is included as supplementary material. Reviewers can verify the proofs by running `lake build` in the proof directory.

Reproducibility: Install OpenHCS via `pip install openhcs` to observe the H-axis behaviors described in Section 5 (click-to-provenance navigation, flash propagation).

A Completeness and Robustness Analysis

This appendix provides detailed analysis addressing potential concerns about the scope, applicability, and completeness of our results.

A.1 Comprehensive Concern Analysis

We identify the major categories of potential concerns and demonstrate why each does not affect our conclusions.

Potential Concern	Formal Analysis
“Model is incomplete”	Theorem 3.32 (Model Completeness)
“Duck typing has tradeoffs”	Theorems 3.34-3.36 (Capability Comparison)
“Axioms are assumptive”	Lemma 3.37 (Axiom is Definitional)
“Clever extension could fix it”	Theorem 3.39 (Extension Impossibility)
“What about generics?”	Theorems 3.43-3.48, Table 2.2 (Parameterized N)
“Erasure changes things”	Theorems 3.46-3.47 (Compile-Time Type Checking)
“Only works for some languages”	Theorem 3.47 (8 languages), Remark 3.49 (exotic features)
“What about intersection/union types?”	Remark 3.49 (still two axes)
“What about row polymorphism?”	Remark 3.49 (pure S, loses capabilities)
“What about higher-kinded types?”	Remark 3.49 (parameterized N)
“Only applies to greenfield”	Theorem 2.10j (Adapters eliminate retrofit exception)
“Legacy codebases are different”	Corollary 3.51 (sacrifice, not alternative)
“Claims are too broad”	Non-Claims 3.41-3.42 (true scope limits)
“Dominance \neq migration”	Theorem 3.55 (Dominance \neq Migration)
“Greenfield is undefined”	Definitions 3.57-3.58, Theorem 3.59
“Provenance requirement is circular”	Theorem 3.61 (Provenance Detection)

A.2 Detailed Analysis of Each Concern

We expand the most common concerns below; the remaining items in the table above are direct corollaries of the referenced results.

Concern 1: Model Completeness. *Potential concern:* The (B, S) model may fail to capture relevant aspects of type systems.

Analysis: Theorem 3.5 establishes model completeness by constitutive definition. In Python, `type(name, bases, namespace)` is the universal type constructor. A type does not merely *have* (B, S) ; a type *is* (B, S) . Any computable function over types is therefore definitionally a function of this triple. Properties like `__mro__` or `__module__` are not counterexamples: they are derived from or stored within (B, S) . This is definitional closure, not empirical enumeration. No “fourth axis” can exist because the triple is constitutive.

Concern 2: Duck Typing Tradeoffs. *Potential concern:* Duck typing has flexibility that nominal typing lacks.

Analysis: Theorems 3.34-3.36 establish that nominal typing provides a strict superset of duck typing capabilities. Duck typing’s “acceptance” of structurally-equivalent types is not a capability: it is the *absence* of the capability to distinguish them. We treat “capability” as the set of definable operations/predicates available to the system, not the cost of retrofitting legacy code; migration/retrofit cost is handled separately (Theorem 3.5, adapter results in Theorem 2.4).

Concern 3: Axiom Circularity. *Potential concern:* The axioms are chosen to guarantee the conclusion.

Analysis: Lemma 3.5 establishes that the axiom “shape-based typing treats same-namespace types identically” is not an assumption: it is the *definition* of shape-based typing (Definition 2.10).

Concern 4: Future Extensions. *Potential concern:* A clever extension to duck typing could recover provenance.

Analysis: Theorem 3.5 proves that any computable extension over $\{N, S\}$ alone cannot recover provenance. The limitation is structural, not technical. A common response is “just check `type(x)`”, but this proves the point: inspecting `type(x)` consults the type’s identity (N) or inheritance (B). Once you consult N or B , you have left shape-only duck typing and moved to nominal or named-structural typing. The “fix” is the adoption of our thesis.

Concern 5: Generics and Parametric Polymorphism. *Potential concern:* The model doesn’t handle generics.

Analysis: Theorems 3.43-3.48 establish that generics preserve the axis structure. Type parameters are a refinement of N , not additional information orthogonal to (B, S) .

Concern 6: Single Codebase Evidence. *Potential concern:* Evidence is from one codebase (OpenHCS).

Analysis: This objection conflates existential witnesses with premises. A category error. In logic, a premise is something the conclusion depends on; an existential witness demonstrates satisfiability.

The dominance theorems are proven from the *definition* of shape-based typing (Lemma 3.5: the axiom is definitional). Examine the proof of Theorem 3.2 (Provenance Impossibility): it proceeds by showing that (S) contains insufficient information to compute provenance. This is an information-theoretic argument that references no codebase. You could prove this theorem before any codebase existed.

OpenHCS appears only to demonstrate that the four capabilities are *achievable*. That a real system uses provenance, identity, enumeration, and conflict resolution. This is an existence proof (“such systems exist”), not a premise (“if OpenHCS works, then the theorems hold”).

Analogy: Proving “comparison-based sorting requires $\Omega(n \log n)$ comparisons” does not require testing on multiple arrays. The proof is structural. Exhibiting quicksort demonstrates the bound is achievable, not that the theorem is true. Similarly, our theorems follow from (B, S) structure; OpenHCS demonstrates achievability.

Concern 7: Scope Confusion. *Potential concern:* Discipline dominance implies migration recommendation.

Analysis: Theorem 3.5 formally proves that Pareto dominance of discipline A over B does NOT imply that migrating from B to A is beneficial for all codebases. Dominance is codebase-independent; migration cost is codebase-dependent.

A.3 Formal Verification Status

All core theorems are machine-checked in Lean 4:

- 2600+ lines of Lean code
- 127 theorems verified
- 0 sorry placeholders
- 0 axioms beyond standard Lean foundations

The Lean formalization is publicly available for verification.

B Historical and Methodological Context

B.1 On the Treatment of Defaults

Duck typing was accepted as “Pythonic” without formal justification. This asymmetry (conventions often require no proof, while changing conventions demands proof) is a methodological observation about community standards, not a logical requirement. The theorems in this paper provide the formal foundation that was absent from the original adoption of duck typing as a default.

B.2 Why Formal Treatment Was Delayed

Prior work established qualitative foundations (Malayeri & Aldrich 2008, 2009; Abdelgawad & Cartwright 2014; Abdelgawad 2016). We provide the first machine-verified formal treatment of typing discipline selection.
